Steel Wire Ropes for Oil-well Drilling.

Wire ropes are largely employed in drilling oil-wells, particularly where the American system of drilling is in use, which is known as the Californian Cable Rig. This system uses a drilling line for manipulating the tools, a casing line for manipulating the casing, and a sand line for cleaning out the wells. The two former are generally 6 × 19 construction, and the latter 6 × 7.

The Russian or Galician system employs jointed rods in place of drilling lines, but wire ropes are used for cleaning out the wells and for manipulating the casing and the string of tools. The sand, pump, or bailing lines are usually 6 × 7 construction, and the other ropes, which run up to $1\frac{1}{2}$ ins. diameter, are 6 × 19, 6 × 24, or 6 × 30.

Oil-well drilling, being exceptionally severe, calls for ropes of high quality.

Galvanized ropes are sometimes advisable on account of the corrosive action of the water in the wells.

It is a matter of general practice to have the drilling ropes left-hand lay.

Pumps and Pumping.

Cornish pumps from 4 ft. to 12 ft. stroke, 6 ins. to 30 ins. diameter, 12 to 16 strokes per min.; piston speeds vary from 60 to 120 ft. per min. A rule sometimes adopted is that speed in feet per second = $\sqrt{l}$, where l is the length of stroke in feet. Ram pumps work at speeds of 100 to 200 ft. per minute.

If n be number of complete strokes (i.e. up and down strokes) per min., and d the diameter of the ram or bucket, the theoretical discharge G in gallons per min. is given by $G = 0{\cdot}034d^2\ n.l.$ The actual discharge is less than this by the slip, which ranges from 3 per cent. to 30 per cent.

* Printed and published by H.M. Stationery Office. Price 1*s.* net; 1*s.* 2*d.* post free.

in extreme cases. In practice it is usually between 10 per cent. and 15 per cent. It must be deducted from the theoretical discharge to get the actual discharge. Maximum velocity of water in rising main 200 to 300 ft. per min., rarely exceeds 100 ft. in small pumps; maximum velocity in windbore, 40 ft. per min.

Pressure at bottom of rising main = pressure due to static head + pressure required to overcome resistance of pipe.

If v be the velocity of discharge in feet per second, H the vertical head in feet, L the length in feet of the pipe, D its diameter in inches, and P the total pressure at bottom of rising main, then,

$$P = 0{\cdot}341\, D^2 \left(H + 0{\cdot}024 \left(\frac{L}{12D}\right)^4 \frac{v^2}{2g}\right).$$

The pressure in the steam cylinder must be capable of overcoming this pressure, allowing for the mechanical efficiency of the engine (say 0·66).

The content of a pipe in gallons of water = $0{\cdot}034\, D^2L$.

The thickness of a pipe can be calculated thus :—

Thickness in inches = 0·000125 P.D. + 0·5.

Thickness of pump-barrel = $0{\cdot}5 + \frac{P.D.}{2{,}000}$, where P is pressure in lbs. per sq. in.

Weight of pipe in lbs. = $2{\cdot}5\ L\ (D^2 - d^2)$, where D and d are external and internal diameters. The flange = weight of 1 ft. of pipe.

Horse-power in the water lifted = $\frac{g\ H}{3{,}300}$, where g is the actual delivery in gallons per min.

The 'duty' of a Cornish pumping engine is the number of millions of pounds of water lifted one foot high by the consumption of 112 lbs. of coal (before 1856 of one bushel=94 lbs., and in America of 100 lbs. of coal) under the boilers. To convert duty into lbs. of coal burnt per h.p. in the water, divide 222 by the duty. It is always theoretical discharge that is taken in calculating duty. Cornish engines have worked with as little as 1·5 lb. coal per h.p.; 2·5 to 3 lbs. is a usual figure.

For double-acting pumps the formula for discharge previously given becomes

$$G = 0{\cdot}068\ d^2\, n.l.$$

If A be the area of the piston, n number of strokes per minute, S length of stroke, b the height of the water barometer, l the length of the windbore, a its area, h the vertical height of the suction lift, g the acceleration of gravity,

$$a > 0{\cdot}0055\ \frac{An^2\,Sl}{g(b-h)}$$ for single-acting pumps, and $> 0{\cdot}00275\ \frac{An^2\,Sl}{g(b-h)}$ for double-acting pumps,

or the piston will rise faster than the water can follow it, and hammering will result.

The air-vessel should have a volume = 4 times that of barrel for single-acting, and 1·6 times for double-acting pumps. (*Weisbach.*)

Centrifugal Pumps.

Let u be peripheral velocity of impeller in ft. per sec.

r radius of the impeller in feet.

n number of revolutions per second.

d depth of openings in impeller in feet.

i number of impellers in series.

h height of total lift in feet.

then

$u = 2\,n\,\pi\,r$. Velocity of radial water discharge from impeller = K u, where K is a coefficient between 0·1 and 0·3, averaging 0·2. Quantity of water discharged per second = $K\ u\ 2\ \pi\ r\ d = 4\ K\ n\ \pi^2\ r^2\ d$ cub. ft. $h = c\,i\,\frac{u^2}{2g}$, where c is a coefficient that varies considerably, but is mostly between 0·75 and 1.

Mechanical efficiency (m) is between 0·5 and 0·8, usually about 0·7.

Hence h.p. required $= \frac{8\ K\ c\ \pi^4\ n^3\ r^4\ i\ d}{8{\cdot}8\ m\ g}$, or taking average values h.p. = about $\frac{2}{3}\ n^3\ r^4\ i\ d$.

Direct coupled motor-driven centrifugal pumps to pump 1,500 gallons p.m. to a height of 1,000 ft. have been found to have an overall efficiency of 71·6 per cent.; electrically driven ram pumps would have a similar efficiency of 80 per cent. (*Prest & Leggat.*)

(See also PUMPS, page 1263.)

VENTILATION.

MINE GASES AND VENTILATION.

Normal air contains 79 vols. nitrogen, 21 vols. oxygen, carbonic acid 0·06 to 0·11 per cent. With 17·0 vols. of oxygen a candle is extinguished, but breathing is still possible; with 15·2 vols. of oxygen breathing becomes more difficult; with 10 vols. of oxygen, very difficult; and with 5 or 6 vols. practically impossible. Prussian rule for volume of air in mines is 70 cubic feet per min. per man underground, reckoning each horse as four men; it must never amount to less than 53 cubic feet per ton of daily output.

Approximately in Great Britain 5·8 tons of air pass through coal mines per ton of coal raised.

The blood in a man's body is capable of absorbing about one pint (about 20 per cent. of its volume) of either oxygen or carbonic oxide when saturated. If it be half saturated with carbonic oxide, unconsciousness sets in, and with higher proportions death follows. In air containing 0·1 per cent. of carbonic oxide the blood would become half saturated in about an hour in the case of a man at rest, and in about half an hour in the case of a man taking exercise. Anything above 0·15 per cent. of carbonic oxide must be considered dangerous; 0·16 per cent. will cause slight distress to mice in an hour, 0·2 per cent. distress in 8 minutes, 0·3 per cent. distress in 4 minutes, 0·45 per cent. distress in 2 minutes and collapse in 4 minutes, 0·57 per cent. distress in 1 minute, collapse in 6½ minutes, and death in 12½ minutes. With canaries 0·09 per cent. causes distress in one hour, 0·15 per cent. distress in 3 minutes, fall from perch in 18 minutes, 0·2 per cent. distress in 1½ minutes, fall from perch in 5 minutes, and 0·3 per cent. fall from perch in 2½ minutes.

Fire-damp.—Fire-damp consists essentially (up to 95 per cent. or more) of marsh gas or methane, CH_4, the remainder consisting of nitrogen and carbonic acid; hydrogen and some of the higher hydrocarbons have also been found in some samples. Haller and Moureu have found helium with traces of neon (0·003–0·05 per cent.), and argon with traces of krypton and xenon (0·003–0·04 per cent.) in fire-damp. A mixture of air and marsh gas will explode if the mixture contains between 5 and 15 per cent. of marsh gas by volume. The maximum of explosive violence is attained with 9 to 10 per cent. of marsh gas. The igniting point is between 650° and 750° C., and there is always a perceptible 'lag' or delay in the ignition, the amount of which depends upon the temperature. According to Taffanel and Le Floch, mixtures containing only 3 per cent. of marsh gas will ignite at 680° C. and as much as 30 per cent. at 875°. In a mixture of 6·5 per cent. of marsh gas with air, the quantity of gas burnt per second varies from 0·00075 per cent. at 535° C. to 0·05 per cent. at 640° C. According to H. Le Chatelier the igniting point of acetylene is 450° C., hydrogen 550° C., methane and carbonic oxide 650° C. The velocity of propagation of ignition of methane ranges from 0·03 m. per sec. with 6 per cent. of methane to a maximum of 0·61 m. per sec. with 12 per cent., and falls again to 0·1 m. per sec. with 16 per cent. of methane in air. The velocity of the explosive wave in a mixture of methane with pure oxygen is 2,500 m. per sec. Marsh gas has been given off in quantities up to 4,500 cubic feet per ton of coal wrought, and has been shown to exist in coal under pressures up to 40 atmospheres. It is on record that in one mine as much as four million cubic feet of fire-damp has been given off in 24 hours.

Experiments on the ignition of mixtures of methane and air by electric sparks have been recorded by Dr. Thornton (*Trans. Inst. Min. Eng.*, xliv. p. 145, and xlvi. p. 112); the most inflammable mixture is one containing about 7 per cent. of methane. With sparks between copper poles the least continuous current capable of igniting a 9 per cent. mixture was found to be:—

50	100	240	480 volts.
4·0	0·9	0·175	0·05 amps.

With iron poles slightly greater currents are required. With alternating currents of low periodicity, the current required is far greater, ranging from 3 times at 50 volts to 12½ times at 500 volts. The higher the frequency, the larger the current required for ignition.

PRINCIPLES OF VENTILATION.

The difference of pressure producing ventilating currents in mines is measured by the water-gauge; a column of 1 in. of water corresponds to about 66 ft. of air at 60° F. and 30 ins. of baro-

metric pressure. The theoretical velocity of air due to such pressure is given by the expression $v=66\sqrt{h}$, where v is the velocity in feet per second and h the water-gauge in inches. If the friction in the airways of a mine is taken into account, according to Murgue—

$$h = K\,\frac{l\,p\,v^2}{a} \text{ or } h = K\frac{l\,p\,Q^2}{a^3}$$

where l is the length of the air passage, p its perimeter, a its area, all in feet, and Q the quantity of air in cubic feet per second. Values of coefficient K: for drifts, bricked and arched, K=0·000,0012; in ordinary rock, untimbered, K=0·000,0034; timbered in the usual way, dimensions taken inside timbers, K = 0·000,0057. If the quantities and velocities be given in thousands of feet per minute, these coefficients become 0·00033, 0·00094 and 0·00156 respectively; some engineers use Mr. Fairley's coefficient, which is 0·002. The critical velocity of air flowing in circular pipes $= \frac{18}{D}$ feet per min., where D is the diameter of the pipe in feet.

The work required to move a quantity Q of air under a water-gauge of h inches=5·2 hQ foot-pounds.

Mr. J. T. Storrow has found that the quantity of air flowing through material under 0·25 in. in size at a slow rate varies directly with the pressure and not with the square root.

(*Trans. Inst. Min. Eng.*, lv. 313.)

The loss by scaling through packwalls, etc., would therefore be greater than in an open airway for the same difference in pressure.

Measurement of flow of air. — In a pipe circular in section a velocity equal to the mean flow is at 0·15 of radius from the wall of the pipe. In a mine drift the mean of two measurements halfway between roof and floor and one-sixth of the width of the airway from either side will approximate to the mean velocity of the air in the drift. The mean velocity is between 0·7 and 0·85 of the maximum velocity at the centre of the drift, averaging 0·78.

With the ordinary plain Pitot tube, if v be the velocity of airflow in feet per second and h the water-gauge in inches, $v=66\sqrt{h}$; with the double Pitot tube (one branch facing the other pointing in the direction of the flow) $v = 56{\cdot}5\sqrt{h}$.

If the pressure of air on either side of a regulator or other diaphragm with an aperture of a square feet be determined by water-gauge, and the difference of gauge pressure be d inches, the quantity of air flowing is $40\,a\sqrt{d}$ cubic feet.

Natural Ventilation and Furnace Ventilation.

Natural Ventilation and Furnace Ventilation.—If there be two shafts, the mean temperature of the air in each of which is respectively T and t (in degrees Fahrenheit), the water-gauge due to this difference of temperature will be $\frac{H}{66}\left(\frac{T-t}{459+T}\right)$, where H is the depth of the pit, assuming that the temperature of the atmosphere is 60° and the pressure 30 ins., under which conditions a cubic foot of air weighs 0·0765 lb.; under any barometric pressure of β inches and temperature t° Fahrenheit, the weight of a cubic foot of air is $\frac{1{\cdot}326\,\beta}{459+t}$, by means of which formula the necessary correction can be applied. The number of heat units required to produce the above water-gauge will be $\frac{1{\cdot}326\ Q\ \beta\ (T-t)}{459+t} \times 0{\cdot}2375 = \frac{0{\cdot}315\ Q\ \beta\ (T-t)}{459+t}$ heat units per second.

The grate area is often taken $= \frac{34}{\sqrt{H}} \times \frac{5{\cdot}2\,hQ}{550}$ sq. ft.

In practice, to pass 300,000 cubic feet of air per min. with a 2-in. water-gauge about one ton of coal is burnt per hour.

Fan Ventilation.

Fan ventilation.—If u be the peripheral velocity of the fan blades in feet per second, the theoretical water-gauge produced $= \frac{u^2}{68g} = \frac{u^2}{2180}$.

The manometrical efficiency of a fan ranges from about 0·45 for an open-running fan up to about 0·9 for a good modern enclosed fan.

The volumetric efficiency under given conditions is the volume of air actually passed by the fan divided by the volume of the fan × number of revolutions.

The mechanical efficiency is the horse-power required to drive the fan (or the fan and fan-engine, as the case may be) divided by the horse-power in the quantity of air moved = $\frac{5{\cdot}2\ hQ}{550}$. It varies from about 45 to about 75 per cent. in different types of fans.

The equivalent orifice of a mine $o = 0{\cdot}4\ \frac{q}{\sqrt{h}}$, where q represents the quantity of air in thousands of feet per minute, and o the area in sq. ft. The equivalent orifice of British mines is usually between 20 and 30 sq. ft.

If H be the initial water-gauge of a given fan (maximum water-gauge, produced on exhausting out of a closed vessel), the equivalent orifice of a fan, working on a mine with equivalent orifice o, should be $= o\sqrt{\frac{h}{H-h}}$. The inlet area of a fan should be about 20 per cent. greater than its equivalent orifice. The equivalent orifice of a fan should be about three times that of the mine on which it works. The velocity at which air enters the fan orifice should be between 1,000 and 1,500 ft. per min. If k be the manometric efficiency of any fan, according to Murgue—

$$u = \sqrt{\frac{g\ 68\ h}{k}}$$

To find the horse-power of a motor or engine required to drive a fan under average mine conditions, multiply the number of cubic feet of air by the water-gauge and divide this product by 4,500. Example: If a fan is delivering 100,000 cub. ft. of air at 2-in. water-gauge, what should be the horse-power of the motor or engine required to drive it?

$$\text{H.P.} = \frac{100{,}000 \times 2}{4{,}500} = 44{\cdot}4.$$ (*Machinery.*)

The average consumption of brattice cloth in U.S.A. is 1,697 sq. yds. per 100 tons of coal raised. (*Report on Brattice Cloth, U.S.A. Bureau of Mines.*)

REGULATORS.

Regulators.—If A be the area in sq. ft. of a regulator which is required to produce as much resistance to the flow of air as a roadway of length l, perimeter p, both in feet, a area in sq. ft., K = Murgue's coefficient of friction as above when the quantity of air is expressed in thousands of cubic feet per minute and the pressure in inches of water-gauge, then $A = 0{\cdot}4\sqrt{\frac{a^3}{K\,p\,l}}$. The regulator should be placed behind the last man in the split.

Safety Lamps.

The gauze should contain not less than 784 meshes per square inch.

TABLE SHOWING AVERAGE CANDLE-POWER OF VARIOUS LAMPS (*a*) AT BEGINNING, AND (*b*) AT END OF TEN HOURS' BURNING WITH FIVE DIFFERENT OILS.

TABLE SHOWING COST IN PENCE PER 1,000 LAMPS OF ONE AVERAGE CANDLE-POWER HOUR, WITH DIFFERENT OILS.

Oil.	Marsaut.	Donald.	Mueseler.	Davy.	'Geordie.'	Clanny.	Scotch Davy.	Deflector.
No. 1	11½	22	14½	18	16	11½	17½	11½
No. 2	19½	33¾	32	19	—	—	—	—
No. 3	25½	43	43½	26½	—	—	—	—
No. 4	35	56	59½	42¼	—	—	—	—
No. 5	45¼	73	75¾	43¾	—	—	—	—

The oils used were as follows :—

Oil.	Specific Gravity.	Composition, per Cent.		Cost per Gallon.
		Mineral.	Vegetable.	*s.* *d.*
No. 1	0·820	100	0	0 9
No. 2	0·841	70	30	1 6
No. 3	0·844	50	50	1 9
No. 4	0·865	30	70	2 3
No. 5	0·889	0	100	2 9

Lamps burning benzine of sp. gr. 0·765, costing 1*s.* per gallon, gave the following results :—

	Candle-power.		Cost in pence per 1,000 lamps of one average c.p. hour.
	At Beginning.	At End.	
Wolf	0·99	0·94	16½
Protector	0·72	0·66	25½

Gas Caps.

Gas caps are shown in an ordinary safety lamp with the flame turned down so as just not to show any white light, when introduced into an atmosphere containing small amounts of marsh gas or methane, approximately as follows :—

2 % of marsh gas. Cap ¼ in., just visible except at extreme tip.
3 % " " " ½ in., fully formed.
4 % " " " ¾ in., well defined.
4½% of marsh gas. Cap 1 in., well defined.
5 % " " " 2⅛ ins. " "
5½% " " " 4 ins. " "
6 % " " " fills the safety lamp.

Gas-testing lamps burning alcohol will show clearly as little as 0·2 per cent. of marsh gas.

Coal Dust.

Coal-dust.—Three ounces of coal-dust per cubic yard of gallery space is sufficient to produce an explosive mixture; excess of coal-dust prevents neither the initiation nor the propagation of an explosion. Coal-dust giving less than 12 per cent. of volatile matter is practically incapable of initiating an explosion. At least 50 per cent. of inert stone-dust is required to prevent the initiation of an explosion. If less than 75 per cent. of the dust passes the 200 sieve it is difficult to initiate an explosion. (*Abstracted from the Lievin experiments.*)

The temperature of ignition of coal-dust is about 1,000°C. Mixed with air and introduced into a heated vessel the temperature may be as low as 590°; there is very little lag. (*Taffanel and Le Floch.*)

The General Regulations provide that in all coal mines except anthracite mines and except mines of which the floor, roof, and sides of the road are naturally wet throughout, every road or part of a road shall be treated with incombustible dust in such a manner as to ensure that the dust on the floor, roof, and sides throughout shall never contain more than 50 per cent. of combustible matter, or else they shall be treated with water in such a manner that the dust is always combined with 30 per cent. (by weight) of water. It is provided that the percentage of incombustible dust required by this regulation may be reduced by an amount equivalent to the percentage of water present. The incombustible dust shall contain not less than 50 per cent. of material capable when dry of passing through a sieve with 200 meshes per linear inch. If more than 50 per cent. of dust is used, the percentage of fine material in such dust may be reduced proportionately, but shall not fall below 25 per cent. Representative tests must be made by the management at intervals of not less than one month, and the results posted at the pit head. The method in which the tests are to be made is fully prescribed by the Statutory Orders.

Rescue Apparatus.

There are three main types of rescue apparatus :—

(1) The supply of oxygen is maintained by means of compressed oxygen carried in steel cylinders.

(2) The supply of oxygen is obtained from liquid air.

(3) Oxygen is chemically generated from peroxides, usually sodium-potassium peroxide.

In (1) and (2) the expired carbonic acid is absorbed, usually by caustic soda, in (3) the reagent that evolves the oxygen also absorbs the carbonic acid.

Particulars of some forms are as follows :—

Apparatus.	Weight.	Oxygen Capacity.
	Lbs.	Cubic Feet.
Pneumatogen (Type II.)	14½	5·8
Draeger	36–39	8·9
Shamrock	36	9·7
Fleuss	31	8·0
Weg	About 30	5·3
Proto	37	8·5
Meco	39½	8·5
Salvus	16	3·0
Aerolith	22	?
Aerophor	30	?

It is estimated that 120 cubic inches of oxygen per min. is ample for the severest exercise; a man at rest requires about 15 cubic inches, and climbing hills 90 cubic inches per min. The Aerolith uses liquid air containing about two parts of oxygen to one of nitrogen; it is stated that one gallon is sufficient for three hours' work.

The Aerophor holds 10 lbs. of liquid air, equal to about 125 cubic feet.

The following has been found to be a man's average consumption of oxygen per minute, gas dry, at N.T.P.

Rate of doing Work.	Breathing.			
	Air.		Oxygen.	
	Litres.	Cub. in.	Litres.	Cub. in.
At rest	0·36	22	0·32	19·5
3,000 ft.-lbs. per min.	1·12	68·3	0·97	59·2
6,000 ,, ,,	1·74	106·2	1·54	95
9,000 ,, ,,	2·33	142·2	2·16	131·8

The most economical rate of walking when travelling a flat road and wearing a rescue apparatus—*i.e.* the rate at which a maximum distance can be covered for a given supply of oxygen—is about 2½ miles per hour.

('*Second Report of the Mine Rescue Research Committee of the Department of Scientific and Industrial Research.*')

When the wet-bulb temperature is much above 80°F., a man cannot remain long at work; he can stand a wet-bulb temperature of 120°F. for about five minutes. (*J. S. Haldane.*)

To Detect Carbon Monoxide in the Air.—A Technical Paper (No. 11) of the United States Bureau of Mines suggests the following simple test capable of detecting as little as 0·03 per cent. of carbon monoxide in the air. One or two drops of blood from a pricked finger are diluted with water until this assumes a buff-yellow colour. Some of this discoloured water is placed in two 100 cubic centimetre test tubes, and one of the tubes is to be taken into the mine, where one-half is to be poured away at the place where the air is to be tested, the mine air taking the place of the water poured away. The tube is then to be corked, taken to the surface, and to be shaken for about ten minutes. If the air in the test tube contains CO, the pink colour of the liquid will indicate the presence of hæmoglobin on comparing the tube with the other test tube filled with the normal fluid. Mr. Ivor Graham has shown that carbon monoxide is a normal constituent of the air of coal mines over 1,500 ft. deep, being produced by the slow oxidation of carbonaceous material at the coal face, in the roads and in the goaf; it is usually under 0·005 per cent., but in a few cases 0·012 per cent. has been found.

('*Trans. Inst. Min. Eng.*,' Sept. 1920.)

Spontaneous Combustion.

Work in the Doncaster Coal Owners' Laboratory has shown that the liability of a coal to spontaneous combustion in the goaf depends, other things being equal, upon its capacity for absorbing oxygen. It appears that a coal, 100 grammes of which, ground to 200 mesh, absorbs less than 200 c.c. in 96 hours at 30°C., is only liable to gob fires when the working conditions especially favour the latter. Coals liable to fire absorb over 300 c.c. in the same time. Presence of pyrites, especially when finely divided, increases the liability to spontaneous combustion.

Fire Extinction.

Investigations have been made recently into the scientific side of mud-jet working for fire extinction in colliery workings, and it has been decided that the material of the mud, some of which should be of a lime and some of a clay character, should consist of sifted earth of 5 mm

mesh, boiler ash, dust from the cleaning of blast-furnace gas, and even combustible material, such as the refuse of coal washing, can be added to make up bulk without any risk should nothing more suitable be at hand. In the majority of instances the mud tank can be so placed as to operate by gravity, but steam or compressed air pressure can be used. It has been found that if a tank is placed at a height of, say, 15 yards, it will force the mud a horizontal distance of 150 yards, even allowing for fairly sharp bends in the conducting pipes.

Electric Signalling in Coal Mines.

A circular issued by the Home Office points out that while there is no difficulty in constructing bells and relays that will comply with the requirements laid down—i.e. which will not 'spark'—most of those in ordinary use in coal mines do not comply with the provision of General Regulation 132; and it states that in mines to which this regulation applies steps must be taken without delay to bring into compliance with the regulation any existing installations which do not already comply, while no new apparatus must be installed except such as does strictly comply. The fact is emphasised in the report that with the usual type of bell and magnitude of battery at present employed, nearly every break-flash that occurs when the bare signal wires are separated would ignite a mixture of firedamp and air containing between 7·5 and 9·5 per cent. of methane, were such a mixture to surround the wires at the time.

Relays, although not requiring for their action so great a battery power as bells, have owing to their higher inductance a lower 'igniting-current' at which the break-flash on the signal wires becomes dangerous. At the present time, with few exceptions, the battery power used on relays is in excess of that sufficient to give a dangerous break-flash at the signal wires. The commonest kinds of relays are dangerous when used with a battery of more than four wet Leclanché cells, or with any current in excess of the current given by such a battery.

The report shows in detail how the bare wire system of electrical signalling as commonly employed can be rendered quite secure from any danger of the ignition of inflammable gases by the break-flash at the signal wires or at the contacts of the signalling instruments.

In order to secure a safe bare-wire signalling system it is necessary in the first place that the battery power employed on any one circuit should be limited, and, in the second place, that the signalling instrument, whether bell or relay, should comply with certain requirements set out in the report.

The maximum pressure allowed by the General Regulation (No. 134 (a)) for a signalling circuit is 25 volts, and from the point of view of safety a pressure of 25 volts is not excessive, provided that, as is usual, wet Leclanché cells (quart size) are employed.

Systems in which the battery used consists of dry primary cells or secondary cells, or in which continuous or alternating current generators are employed, can be rendered safe if, in addition to the use of anti-sparking devices, sufficient non-inductive resistances are permanently installed in the circuit.

Both bells and relays should have flame-tight covers (preferably locked), and should be so constructed and maintained that when included in a circuit with a battery at 25 volts the break-flash produced, when bare signal wires are separated after giving a signal, is incapable of igniting an 8 per cent. methane air mixture.

ORE DRESSING AND COAL WASHING.

(For details see 'The Dressing of Minerals,' by Henry Louis, from which the following is mainly abstracted.)

The operations included under the head of dressing comprise all the operations between the extraction of the crude mineral from the mine and rendering it merchantable, thus forming a link between the operations of the miner and the metallurgist. By common consent, gold milling is generally looked upon as a dressing operation, though it is doubtful whether cyanidation should also be included.

The various operations consist of:—

Hand picking or sorting.

Comminution (coarse breaking or crushing and fine breaking or grinding).

Sizing (preliminary or rough sizing and final or fine sizing).

Classifying.

Separation by differences of specific gravity, magnetism, electric conductivity, or surface tension.

Usually a more or less complicated series of operations is required, especially in the case of complex ores, and these are usually indicated by means of flow sheets.

Let the weight of feed any concentration process be A and its assay a per cent., the weight and assay of concentrates be B and b and of tails C and c respectively, then the

$$\text{Enrichment ratio} = \frac{b}{a} = \frac{\%\ \text{Recovery}}{\%\ \text{Concentration}}.$$

$$\% \text{ Concentration} = \frac{100B}{A} = \frac{100(a-c)}{b-c}.$$

$$\% \text{ Recovery} = \frac{100b(a-c)}{a(b-c)} = \frac{B100b}{Aa}. \quad A = \frac{B(b-c)}{a-c}.$$

$$\% \text{ Efficiency of concentration} = 100\frac{B}{A}\left(\frac{b}{a} - \frac{100-b}{100-a}\right) = 100\frac{a-c}{b-c}\left(\frac{b}{a} - \frac{100-b}{100-a}\right) =$$

$$100\,\frac{\% \text{ Recovery} - \% \text{ Concentration}}{\% \text{ Waste in feed}}.$$

(R. T. Hancock.)

Sorting is performed either on floors or on picking belts or tables. An ordinary picking belt may be of iron plates 4 ft. wide, 50 to 100 ft. long, travelling at 40 to 65 ft. per minute. Pickers stand on both sides, 7 ft. to 15 ft. apart; each picker can treat 1–3 tons of coals per hour.

Power required to drive, 2½ to 5 h.p. Upkeep, about 50*l.* per annum.

Rubber-covered canvas belts about 32 ins. wide are also used, and will carry 25 to 50 tons per hour at speeds of 30 to 60 ft. per minute.

Circular tables are 3 to 4 ft. wide, 10 ft. to 18 ft. in diameter, revolving with a peripheral speed of 40 to 60 ft. per minute, and can deal with 30 to 70 tons of mineral per hour.

Comminution.—Rough breaking is done by jaw breakers, either reciprocating like those of the Blake, Dodge, etc., type, or gyrating like the Gates type. The former have been built to take pieces up to 5 ft. by 7 ft., requiring 300 h.p. to drive, and breaking 300 tons per hour. Smaller breakers usually break 1 ton per hour for a consumption of 2–3 h.p. The gyrating crusher is better suited to very large outputs, but cannot take such large pieces, and appears to be rather more economical of power.

Fine Crushing.—Rolls are used for medium and fine crushing. Let r be the radius of the particle to be broken and d the radius of the particles in the crushed product (both considered as spheres); the minimum radius of the roll should be $> 25\,(r - d)$.

For fine crushing to about ¼-in. mesh the following table shows the general practice :—

Rolls.		Revs. per minute.	Horse-power required.	Cwts. crushed per hour.
Diam.	Face.			
10½ ins.	10½ ins.	130	3	25
12½ ,,	10½ ,,	110	4½	45
16 ,,	10½ ,,	90	6½	65
21 ,,	10½ ,,	75	9½	100
27 ,,	11 ,,	45	12½	145
37 ,,	12 ,,	45	16	200

The peripheral speed should be greater the finer the product required; for grinding to 40 mesh the speed should be 1,000 ft. per minute.

In large plants three or four sets of rolls are placed in series so as gradually to reduce the ore to the desired size. At Mount Morgan, such a plant consisted of eight sets of rolls in two series of four, thus :—

26 ins. diam., 15 ins. face, set $\frac{3}{32}$ in. apart, 112 revs. per min.
26 ,, 15 ,, ,, $\frac{1}{16}$,, ,, ,,
30 ,, 16 ,, ,, $\frac{1}{16}$,, ,, ,,
30 ,, 16 ,, ,, in contact ,,

The total power consumption was 100 h.p. and the crushing capacity 125 tons per 24 hours crushed to 20 mesh (0·025 in.); the wear on the steel roll-shells was 0·108 lb. of steel per ton of ore crushed.

Stamps.—The ordinary gravitation stamp is used more largely for gold milling than for other purposes, but also for crushing tinstone, etc. The complete stamp consists of the head, shoe, stem and tappet, the weight of which may be up to 1,500 lbs. The relative weights are about 30, 17, 40, 13. It is lifted by a cam forming the involute of a circle; if h be the lift of

the stamp, r the radius of the pitch circle of the involute, and a the angular motion of the cam during the lift, $h = \frac{\pi r a}{180}$. The speed is usually about 90 drops per minute.

If n be the number of drops per minute, h the drop in inches, s the number of stamps, and w the weight of a stamp in pounds, the power required is approximately $\frac{nhsw}{300{,}000}$. (For a more exact formula see 'A Handbook of Gold Milling,' by H. Louis.) The average crushing capacity is 2–8 tons per 24 hours for a 1,000 lb. stamp. The Husband atmospheric stamp with two heads requires 35 h.p. to work it, and can crush 40 tons of hard tinstone per 24 hours down to 0·048 in.

Steam stamps are used mainly for crushing the copper-bearing rocks of the Lake Superior Mines, down to about $\frac{1}{4}$-in. mesh. One such stamp will crush 10 tons per hour, the efficiency being about 1·75 tons per i.h.p. per 24 hours.

Ball mills have been made both for dry and wet crushing. The Krupp mill is a dry-crushing mill; the No. 5 size, which is largely used, is 86 ins. diameter by 46 ins. length, makes 20–25 r.p.m., weighs 182 cwts., and a set of balls weighs 18 cwts. At Mount Morgan these mills require 13 h.p. and crush 22·7 tons per 24 hours to 20 mesh (0·025 in.). The balls wear at the rate of 0·725 lb. and the hunch plates at the rate of 0·681 lb. per ton of ore crushed.

Wet crushing ball mills are 60 ins. to 80 ins. in diameter and about 40 ins. long. A charge of balls for such a mill weighs about 2 tons; it is run at 25 to 30 r.p.m., takes from 25 to 35 h.p. to drive it, and will crush 25 to 100 tons down to 0·02 mesh per 24 hours; the water consumption is about 65 gallons per minute.

The tube mill is also used wet or dry, and is in effect an elongated ball mill, 3 ft. to 5 ft. in diameter and 13 ft. to 26 ft. long. A tube mill 4 ft. in diameter, 16 ft. 6 ins. long, crushed in Western Australia 38 tons of sand per 24 hours, 95 per cent. of the product being finer than 100 mesh, requiring 30 h.p. to drive it. Such mills are lined with silex, chilled iron, or hard steel bars, and are usually charged with flints. According to Mr. Davidson, the best number of r.p.m. $= 200 \div \sqrt{d}$, where d is the internal diameter in inches; the weight of flints in pounds should be $N \div 44$, where N is the internal capacity of the mill in cubic feet. Western Australian practice corresponds nearly to $N \div 60$.

The Marathon mill uses rods in place of balls; a mill 3 ft. diam., 7 ft. long, charged with 7,000 lbs. of rods $\frac{1}{2}$ in. to 2 in. diam., running at 30 r.p.m., crushed 18 tons per hour with a consumption of 12·5 h.p., using 42 U.S.A. gallons of water per minute. The feed was below $\frac{1}{4}$-in. mesh and the product was ground to $\frac{1}{14}$-in. mesh, 14 per cent. being below $\frac{1}{30}$-in. mesh. The wear of the line plates was 0·14 lb. and of the rods 0·4 lb. per ton of feed.
(*Trans. Amer. Inst. Min. Eng.*, lv., p. 678; lvii., p. 355.)

The Hardinge tube mill has the form of two cones base to base. An 8 ft. Hardinge mill requires 50 h.p. to drive it, and requires about 10 h.p. hours per ton crushed to about 48 mesh.

An 8 ft. × 22 ft. mill crushed 200–250 tons per 24 hrs. using about 56 h.p., with a charge of 5 tons of Danish pebbles wearing at the rate of 2·16 lbs. per ton of feed; with steel balls instead of pebbles 360–400 tons were crushed per 24 hours.
(*Trans. Amer. Inst. Min. Eng.*, lv., p. 678.)

The Marcy mill is a short mill (5–6 ft.) with perforated diaphragm at the discharge end, from 2 ins. to 48 mesh. An 8 ft. by 6 ft. mill driven by a 225 h.p. motor crushes 550 tons per 24 hours at 24 r.p.m., carrying 30,000 lbs. chrome-steel balls.
(*C. T. Van Winkle, Trans. Amer. Inst. Min. Eng.*, vol. lix. (1918), p. 227.)

The Huntingdon mill is made in three sizes, 3 ft. 6 ins., 5 ft. and 6 ft. diam.; No. 2 is most used; it weighs about 5 tons; consumes 12 h.p.; makes 60–70 r.p.m., and will crush about 10 tons per 24 hours to about 15 mesh.

The Arrastra is 10 to 20 ft. in diameter, has usually four dragstones, 6–8 cwts. in weight At 6 to 12 r.p.m. a charge of 1 to 3 tons is ground in 2–3 hours.

The Chilian mill has 2–3 rollers, 4 to 6 ft. in diameter, takes up to 75 h.p., and crushes up to 150 tons per 24 hours.

Sizing.—For coarse screening fixed grizzlies or 'jigging' screens are used. For medium and fine screening mostly trommels, 8 ft. to 2 ft. in diameter by 12 ft. to 3 ft. long; the peripheral velocity is usually 50 to 200 ft. per minute. The slopes may vary from 5° to 14°, averaging about 7°. A set of seven trommels, 3 ft. diam., 5 ft. long, will size about 7 tons of ordinary crushed material per hour, and require up to 5 h.p. to drive it.

Classification.—This term applies to the separation into groups of equal falling particles. The terminal velocity of a particle falling freely in water is approximately $V = 2{\cdot}6\sqrt{D(S-1)}$, where V is the velocity in metres per second, D the diameter in metres of the screen mesh through which the particle just passes, and S the density of the mineral. This velocity will be attained

after the particle has fallen a distance equal to $V^2 \div 4$ approximately. When V is less than 0·5 to 1, according to the substance, the law on which these formulas are based (friction $\propto$ velocity^2 and viscosity negligible) no longer holds good. The particles fall more slowly, obey a different physical law, and are known as slimes, which are incapable of classification.

The minimum diameter of a particle that obeys the above law of terminal velocity is

$$\sqrt{\frac{9\,\mu^2}{2\,g\,(s-1)}} \text{ cm.};$$

Where μ is the viscosity (0·0115) and g the acceleration of gravity (981), both in C.G.S. units, and s is the specific gravity of the particle.

Hence log diameter in cm. $= \bar{3}\cdot92764 - \frac{1}{2}\log(s-1)$.

The following table is calculated from the above formula :—

Sp. gr.	Diam. in mm.	Sp. gr.	Diam. in mm.	Sp. gr.	Diam. in mm.	Sp. gr.	Diam. in mm.	Sp. gr.	Diam. in mm.	Sp. gr.	Diam. in mm.
1·2	0·1528	1·6	0·1004	2·0	0·08465	2·4	0·07567	3·5	0·06237	5·5	0·05128
1·3	0·1265	1·7	0·09534	2·1	0·08201	2·5	0·07395	4·0	0·05870	6·0	0·04950
1·4	0·1149	1·8	0·09118	2·2	0·07966	2·6	0·07238	4·5	0·05575		
1·5	0·1071	1·9	0·08768	2·3	0·07757	3·0	0·06719	5·0	0·05333		

Spitzkasten : the first box should be 2 ft. wide for 10 cub. ft. pulp per minute, or 1–2 cwts. of solid matter ; boxes may increase in geometrical progression with factor of 1·5 ; length of first box about 6 ft., increasing by 3 ft. for each successive box.

Trough classifiers 10 to 20 ft. long, 1 ft. wide at narrow end, will treat 100 tons per 24 hours, with 100 cub. ft. of water per ton of crushed material.

Jigs.—The following represents the general modern practice :—

Diam. of particle .	0·25	0·50	0·75	1·00	1·25	1·50	1·75	2·00 ins.
Length of stroke .	0·4	1·2	1·55	1·8	2·0	2·15	2·3	2·4 ,,
No. of strokes per min.	200	160	145	130	125	125	125	125

Continental jigging practice on ordinary lead-zinc ores: three to five compartment jigs; screen surface 20″ × 31·5″.

Size of Particles.	Length of Stroke.	Strokes per Min.	Water per Cwt. treated.	Capacity per Sq. Ft. of Screen Area per Hour.
	Inch.		Gallons.	Cwt.
0·04	0·2	280	90	0·6
0·046 to 0·06	0·25	280	73	0·9

Jig screens of steel wire are liable to rapid corrosion when pyritic ores are being treated ; wire drawn from Ambrac (Cu75Ni20Zn5) has been recommended in such cases.

Round buddle; diam. 18 ft. to 25 ft.; arms 5–10 r.p.m. Capacity 1½–3 cub. ft. per min., carrying 28 to 56 lbs. material; time of filling 3–10 hours.

Slime table; diam. 15 ft. to 25 ft.; ¼–1 r.p.m. Pulp 1½–3 cub. ft. per min., carrying 4 to 7 lbs. per cub. ft. Clear water 1½–3 cub. ft. per min. Power required ½–1½ h.p.

Frue vanner; belt surface 4 ft. by 12 ft.; fall 3 ins. to 6 ins.; travel 6 ft. per min.; strokes 200 per min. Capacity 0·25 to 0·5 cub. ft. pulp per min.; 5 to 8 tons material 24 hours. Clear water ½ of pulp. Power required ½ h.p.

Lühring vanner; belt surface 3 ft. 6 ins. by 12 ft.; travel 8–12 ft. per min.; 160–180 strokes per min. Capacity 2½–7½ tons per 24 hours; clear water 1–2 cub. ft. per min. Power required ¾–1 h.p.

Wilfley table; 16 ft. long, 6 ft. wide, tapering to 3 ft. Will take particles up to ⅛ in. 240 strokes per min., ¾ in. long. Capacity 25 to 50 tons per 24 hours. Clear water 1 to 3 cub. ft. per min. Power required 1 h.p.

Coal Washing.

Coal as it comes from the mine is first screened, usually over a 2 ins. to 2¾ ins. screen; the oversize drops on to picking belts, where shale, dirty coal, etc., is picked out. The undersize is taken to a washery, especially when it is required for coke-making. A jigging screen with ¾-in. holes will screen about 1 ton per hour for each 0·75 sq. ft. of screening surface.

Coal is sometimes dry-cleaned in the spiral separator, in which it is allowed to slide down a spiral track, the clean coal falling over the outer edge, whilst the shale, etc., remains on the track.

When the separation of the clean coal from the accompanying shaly matter is easy, or when the products are not required in the highest possible state of purity, a simple form of washer may be used. Such is, e.g., the Elliott trough washer, capable of treating 5 to 10 tons of small coal per hour with a water consumption of 1,750 gallons per ton of coal washed. The Blackett washer is similar in principle, but the fixed trough with the moving dam-plates is replaced by a revolving drum within which is a spiral baffle-plate; it will treat 10 tons of small coal per hour, requiring 3,000 gallons of water in circulation per ton of coal washed. The Robinson washer works on the principle of a spitzkasten, with upward flow of water and a revolving stirrer; it can treat 15 to 20 tons of small coal per hour.

The purity of the washed coal is usually determined by floating it in solutions of known specific gravity; coal that floats in solutions of sp. gr. 1·35 to 1·45 is considered clean coal. Most plants for such complete washing make use of jigs (bashes or boxes), and the coarser refuse is sometimes crushed and re-washed. See Flow Sheet No. I, p. 2468.

The Coppée Washery is typical of the more usual form of plant. The unwashed coal, say under 2 ins. to 3 ins., is sized before washing. The washing is carried out in two types of boxes, viz.: (*a*) Small coal feldspar boxes, which treat all the coal below ½ in.; (*b*) nut coal type of box, which treats the various sizes below 3 ins. and above ½ in. These sizes vary according to local conditions and the requirements of the market. The nut washers are 8 ft. deep, and the sieves are 5 ft. long and 3 ft. to 5 ft. wide, each washer treating 2·5 to 3·5 tons per hour per foot of width of screen. The more important data affecting the operations of nut washers are shown in the following table:—

Size of Nuts.	Depth of Layer of Shale on Sieve.	Length of Stroke.	No. of Strokes per Minute.	Mesh of Sieve.
¼ in. to ½ in.	2½ ins.	2½ ins.	80	1/10 in.
½ „ „ 1 „	3 „	3 „	75	⅛ „
1 „ „ 2 ins.	3½ „	3½ „	70	¼ „
2 ins. „ 3½ „	4½ „	4½ „	65	3/10 „
3½ „ „ 5 „	5½ „	6½ „	60	3/10 „

The Feldspar Washer is built in two compartments, each 4 ft. long, making a total length of 8 ft. by 2 ft. 6 ins. wide, the box being 5 ft. deep; such a washer can wash 7 to 10 tons of small coal per hour up to ½ in. in size. The following are the leading data:—

	1st Compartment.	2nd Compartment.
Thickness of layer of feldspar	2½ ins.	2½ ins.
„ „ „ shale	2/10 in.	2/10 in.
Size of pieces of feldspar	8/10 in. to 1 in.	6/10 in. to 8/10 in.
Length of stroke	0·55 in.	0·47 in.
No. of strokes per minute	165	165
Mesh of screen	0·55 in.	0·47 in.

A plant to wash 100 tons per hour, 50 per cent. on nut washers and 50 per cent. on feldspar washers, would require four of the former, 4 ft. wide, and six of the latter. Such a plant would require in circulation about 135,000 gallons of water, and make-up water amounting to between 2,800 and 3,500 gallons per hour.

When the refuse from the nut washers contains sufficient intergrown coal to be worth treating, it is crushed, generally in a disintegrator, and the crushed material is re-washed on feldspar washers.

A coal washery may require from 1·5 to 3·5 h.p. for each ton of unwashed coal treated per hour, varying with (*a*) the total output of the washery (a large washery requiring a relatively smaller h.p. per ton); (*b*) the quantity of interstratified coal, and whether the larger size is crushed and washed together with the smaller size, or whether the smaller size only is re-washed; (*c*) the type and capacity of draining and storage bunkers, and whether apparatus is installed for mixing the various products.

Messrs. Simon-Carves, Limited, build washeries on the so-called Baum principle, in which washing precedes classification. The slack below about 2 ins. is delivered to a bash having an area of about 0·8 sq. ft. per ton per hour; the washed coal then passes to a screen of about ⅜-in. mesh; the over-size is clean coal, and the under-size goes to a second bash having an area of about 1 sq. ft. per ton of coal per hour, the product being clean coal and refuse. The dirt produced in the first washing can be further crushed and washed over again if necessary. A plant to treat 100 tons of slack per hour would, therefore, require a first bash with an area of 80 sq. ft., and a second bash with an area of 100 sq. ft.; the water in circulation would be about 130,000 gallons per hour, and the make-up water required about 2,500 gallons.

In the United States small coal is being largely washed on shaking tables of the Wilfley type: such a table will treat 5 to 8 tons per hour of coal under ⅜-in. mesh, requiring about 1 h.p.

The flotation process has been applied to washing fine coal. (See *Trans. Inst. Min. Eng.*, lxvii. p. 374.)

The Chance process employs a separating cone worked with a sludge consisting of sand and water; it is said to give excellent results, and is largely used in the U.S.A.

The American Coal Cleaning Corporation's machine consists of a shaking table with riffles and a porous deck through which a current of air ascends on the principle of the Sutton-Steele table; this cleans dry coal and the finished product contains under 2 per cent. of extrinsic ash. Over 1,000,000 tons of coal were cleaned in this way last year in the U.S.A.

Mr. Norman Kemp has applied X-ray analysis to the products of the coal washery.

Common non-ferrous minerals, e.g. mica, quartz, felspar, calcite, have susceptibilities < 0·000001. 'Strongly' magnetic minerals have susceptibilities > 0·001. 'Feebly' magnetic minerals between 0·001 and 0·0001. (*After Prof. Ernest Wilson.*)

Magnetic separators: (1) For minerals of high magnetic susceptibility:—

Dry working, e.g. Wenström: drum 30 ins. diam., 24 ins. face. Capacity 5–7 tons per hour; will take lumps up to 7 lbs.; 30 r.p.m. Current 15 amperes at 120 volts.

Wet working, e.g. Gröndal: 24 ins. wide, 24 ins. diam., 100 r.p.m. Capacity up to 3·5 tons per hour. Current 10 amperes at 110 volts.

(2) For minerals of low magnetic susceptibility:—

Dry working, e.g. Rowand-Wetherill. Belt 18 ins. wide, three electro-magnets taking respectively 5, 15, and 30 amperes at 110 volts. Capacity, 0·25 to 1 ton per hour.

Wet working, e.g Ulrich.

FLOTATION PROCESSES.

These may be classified as follows :—

I. *Film Flotation*, utilising differences of surface tension on particles at an air-water interface—e.g. De Bavay, Macquisten processes.

II. *Oil Flotation*, utilising differences of surface tension in an oil-water medium where the particles are buoyed up by oil—e.g. First Elmore process.

III. *Adhesive Processes*, utilising differences of surface tension between particles and oil or grease, causing differential adhesion to oiled or greased surfaces—e.g. Murex, Cattermole, greased-plate processes.

IV. *Froth Flotation*, utilising differences of surface tension at gas-water interfaces, where the particles are buoyed up by bubbles of gas :—

(*a*) Where the bubbles are produced by chemical action—e.g. Potter, Delprat processes.

(*b*) Where the bubbles are produced by releasing the air dissolved in water—e.g. Elmore vacuum process.

(*c*) Where the bubbles are produced by mechanical means—e.g. Minerals Separation, Callow, Janey, K. & K. (Kraut & Kolberg), Rork processes.

(See also 'Froth Flotation : its Commercial Application and its Influence on Modern Concentration and Smelting Practice,' Walter Broadbridge, *Bull. Inst. M. M.*, January 1920.)

COSTS OF FLOTATION MACHINES.

(*Ralston.*)

Reagents used :—

Gangue modifying :—Acids, alkalies, silicates, carbonates, and other salts.
Froth producing :—Soluble oils, essential oils, cresylic acid, amyl alcohol, etc.
Froth stabilising :—Insoluble oils, petroleum, etc.

Surface Tension of Liquids against Air

		Dynes per sq. cm.			Dynes per sq. cm.
Water	(at 0° C.)	75·8	Water with 0·14 per cent. cresol	(at 23° C.)	71·5
Water	(,, 20° C.)	75·1	Water with 0·14 per cent. amyl alcohol	(,, 23° C.)	68·4
Phenol	(,, 41° C.)	37·0	Water with 0·134 per cent. saponine	(,, 23° C.)	48·7
Cresol	...	34·8	Water with eucalyptus 'solute'	(,, 20° C.)	44·6
Olive oil	...	32·0			
Petroleum	...	27·7			
Turpentine	...	25·6			

Dilute sulphuric acid reduces the contact angle and hysteresis range of that angle far more for quartz, silicates, and oxides than it does for metallic sulphides; oiling the latter greatly increases the contact angle and the hysteresis range.

(*H. L. Sulman*, 'A Contribution to the Study of Flotation,' *Bull. Inst. Min. Met.*, November 1919.)

The Inspiration Consolidated Copper Company's plant at Miami, Arizona, treats 15,000 tons in 24 hours. The ore contains 1¾ per cent. of copper, mainly in finely disseminated sulphides. Flotation reagents used, 1¾ lbs. per ton of ore. Recovery, 85 per cent. of total copper, 90 per cent. of copper present as sulphide; concentrates contain 20 per cent. of copper.

(*Trans. Amer. Inst. Min. Eng.*, lv., 1916, p. 576.)

Finely-ground coal may be froth-floated from shale, using 1 lb. of cresol and ½ lb. of paraffin per ton of coaly shale; the latter contains about 65 per cent. of ash, the clean coal about 8 per cent.

ELECTROSTATIC SEPARATION is used in some special cases—e.g. for concentrating rosin blende, molybdenite, and graphite (Blake-Marsden and Huff processes).

DRY SEPARATORS, using currents of air instead of water, are used under exceptional conditions.

FLOW SHEETS.

The diagrams given on pp. 2468–2474 are specimen flow sheets, illustrating the sequence of operations in certain typical cases :—

I. Coking coal. II. Low grade magnetic iron ore. III. Quartz carrying cupriferous pyrites. IV. Lake Superior copper ore. V. Lead ore. VI. Tinstone containing wolfram. VII. and VIII. Copper ore by Froth Flotation.

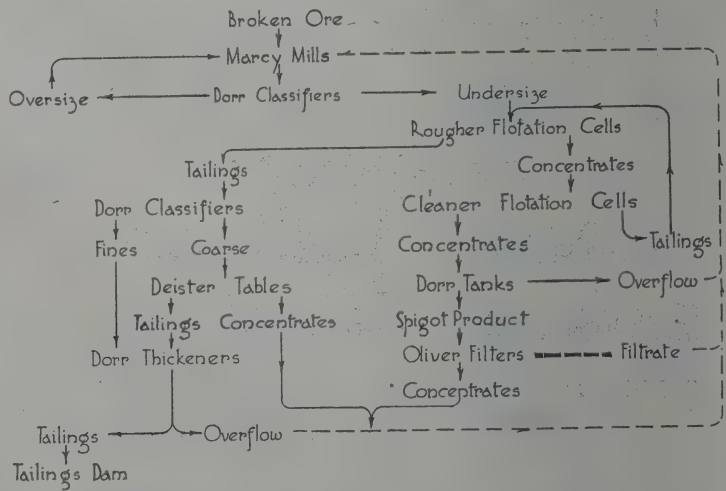
FLOW SHEET VIII.

Where the Frothing Agent is added during Grinding.



GOLD MILLING.

With the improvements in the cyanide practice and also with the exhaustion of the rich free milling surface ores of various camps, which rendered such improvements necessary, have come changes in the process of treating gold ores. Instead of the simple Californian practice of crushing by 900 lb. stamps to about 40 mesh, amalgamating either in or outside the battery, concentrating the sulphides on vanners or shaking tables, chlorinating the concentrates, and sometimes treating the tailings by cyanidation, the 'all-sliming' process has come into force.

As practised on the Rand, the ore is screened through grizzlies with bars 2¾ ins. apart, the oversize going to a sorting belt, thence to a crusher. The ore passes into a feeder, thence to stamps weighing 2,000 lbs. per head, where it is crushed to pass a 10-mesh discharge screen. The pulp is classified in cones and the coarse product delivered to tube mills where it is slimed. The product of the tube mills, together with the overflow from the classifying cones, is delivered to the amalgamating tables. From the tables it is again classified, the sands being cyanided direct, and the slimes treated by air agitation, then filter-pressed or vacuum-filtered.

The most vital changes from the old practice to the new have been: the use of the heavy gravity stamp merely as a preliminary coarse crusher for the tube mills; the adoption of the tube mills for fine grinding and the employment of the tall, air-agitation tanks and of filters.

The practice is modified in each district, the modification depending largely upon the nature of the ore. In some camps silver ores are being successfully treated by fine crushing and cyaniding.

Stamps.

The duty of stamps depends upon the nature of the ore, the weight of the stamp, its speed and drop, the size of the aperture of discharge screen, and the height of the discharge. The following table gives the duty per stamp in various districts :—

DUTY OF STAMPS.

Mine or District.	Weight of Stamp.	Drop in Inches	Number of drops per Min.	Screen Aperture.	Discharge in Inches.	Tons Crushed per head per 24 Hrs.	Remarks.
California . .	900 lbs.	7	90	900 per sq. in.	4	3	Gold Quartz
Melones, Cal. .	1,000 ,,	7	104	20 mesh	—	4·41	
Tonopah Mill, U.S.A.	1,050 ,,	6½	104	slot ·04 in. wide	2½	5·09	Gold and Silver
Montana-Tonopah, U.S.A.	1,050 ,,	7	100	20 mesh	3	3·3	Gold and Silver
Tonopah Belmont, U.S.A.	1,050 ,,	6	104	24 mesh	—	3·7	,,
Goldfield, U.S.A..	1,050 ,,	7	108	12 mesh	—	6	,,
Komata Reefs Mine	1,030 ,,	6½	100	4½ holes per in.	4	5	Gold
Luipaards Vlei Rand	1,629 ,,	8½	98·6	200 holes per sq. in.	4	9·6	,,
Simmer & Jack East	1,550 ,,	8	96	200 holes per sq. in.	3½	8·3	,,
Waihi Grand Junction	1,110 ,,	7	105	5 to 10 mesh	1½	7·6	,,
Oroya Brownhill.	1,100 ,,	7¾	108	10 mesh	2	6·48	,,
Ivanhoe . .	1,192 ,,	7½	104	225 mesh	2	5½	,,
Gt. Fingall . .	1,150 ,,	8	106	12 mesh	3	7	,,
Mysore Gold Mine, Mysore, India	1,150 ,,	7·5	96	1,200, 625 and 400 per sq. in.	3	3·63	,,

It is claimed that the new 2,000 lb. stamps of the Goldfield (S.A.) are capable of crushing 26 tons of ore per stamp per 24 hours by introducing an elimination screen to 'bypass' the fine material from the rock bins direct to the tube mill and using screens with aperture of ·284 inch.

Amount of water varies on the Rand, from 5 to 10 tons of battery water to one of ore, depending upon the duty. In Western Australia the amount of water required is 4 to 8 gallons of water per stamp per minute.

Power per stamp.—The 2,000 lb. stamp requires 5 h.p. per stamp. In Nevada, for 1,250 lb. stamp 3·5 h.p. per stamp is used. At the Goldfield Con. in Nevada with 140 stamps, fine grinding and cyaniding, 1,500 h.p. is supplied to the mill or 1·73 h.p. per ton of ore milled.

Cost of Equipment of Gold Mills.

The following is the comparative cost of gold mills, including all machinery and buildings :—

Mill.	Number of Stamps.	Cost of Machinery and Plant.	Cost per Stamp.
Rand Mill	200	£334,000	£1,670
New Kleinfontein	200	420,480	2,102
Wit Deep	200	346,210	1,731
Robinson Central Deep	100 and Tube Mill	234,013	2,340
Great Fingall	,,	193,745	1,937
El Oro	,,	160,000	1,600

In Nevada, the cost of complete plants doing fine grinding and slimes filtering is 1,400*l.* a stamp.

Tube Mills

are used as secondary crushers following the stamps. On the Rand they are most efficient when fed with ore that has been crushed through a screen the apertures of which are ·27 in. or say ¼ in. They are here 25 feet in length by 5½ feet in diameter, and one tube mill crushes the product of 10 stamps. Each tube mill requires 100 h.p. to drive it. In New Zealand tube mills are 16 ft. by 4 ft. revolving at 29 r.p.m., and driven by 25 h.p. motor. The feed is 1½ parts of water by weight to 1 part of ore. In 22 months a tube mill ground 28,500 tons of hard quartz, 50 per cent. of which passed through a 200-mesh screen.

At Pachuca 90 h.p. is used for a 5 ft. 6 ins. by 22 ft. tube mill. Output 140 tons per day through a 60-mesh screen.

At Waihi Grand Junction tube mills 19 ft. 3 ins. long by 4 ft. 8 ins. diameter require 42 h.p. Those 16 ft. 3 ins. long by 4 ft. 3 ins. diameter require 25 h.p. They consume 2·89 lbs. of flint pebbles per ton of ore crushed at stamps. They are run at 27 r.p.m.

Chilian Mills.

Chilian mills are employed either for crushing preliminary to amalgamation, in which case the gold is partly amalgamated in the mill itself, or they are used in lieu of the tube mill as fine grinders following the stamps.

For crushing ores for direct amalgamation the so-called slow speed Chilian mills are well adapted. Machines of this type are extensively employed in Russia and Siberia. They are expensive in first cost, but the power, labour, and repair costs are very low. Furthermore they are notable for their simplicity, requiring little close or skilled attention.

A slow speed Chilian mill was employed in California on hard close quartzose gold ore. It ran at 8 to 10 r.p.m. It had four runners each weighing 1,200 lbs. travelling on a steel die 3 ins. thick with 5 ins. face and 7 ft. outside diameter, 4½ tons of rock in a tank above and sustained by the axles giving additional crushing weight. Twenty tons of ore per 24 hours were crushed with a 4 in. discharge, and 88·1 per cent. extraction obtained 0·85 per cent. of the ore passed through a 100-mesh screen. One man per shift handled the mill. Cost of ore crushed 6*s.* per ton. Gasoline power was used consuming under heaviest load 2·17 gallons of distillate per hour. (*A. McLaren.*)

The standard type of Chilian mills used in Russia is 7 ft. to 10½ ft. in diameter with 2 runners 5½ to 6½ ft. in diameter, and from 7 to 12 ins. in width. The speed is 11 r.p.m. The discharge is 8 to 10 ins. Feed is about 1 in. and discharge screen slotted. The water is 6·5 to 10·1 times the ore in weight and duty is 16 to 24 tons per 24 hours. The power required is 7 to 12 h.p.

Rapid-running Chilian mills were used as fine grinders after the stamps in the Goldfield Consolidated mill in Nevada on fairly soft ore. There 140 stamps were in operation and six 6 ft. Chilian mills crushing from 4-mesh to 16-mesh were installed. These were operated at 32 r.p.m. Their capacity was 75 tons per 24 hours and the power required 35 h.p. each. The cost of crushing by these mills is given at 5*d.* per ton of ore milled. (*J. W. Hutchinson.*)

At Cripple Creek a 6-ft. Chilian mill running at 33 r.p.m. reduces 4 tons of ore per hour, 60 per cent. of which will pass a 150-mesh screen. The feed passed a ⅜-in. aperture.

Rolls.

Where a relatively small tonnage is to be crushed coarse, as for example when coarse concentration is employed or where the ore is porous and is cyanided coarse, it is the practice to use rolls. They are cheaper than gravity-stamps in first cost, repairs, labour, and power, and are not complicated by screens.

In South Dakota the ore, a hard, close-grained Cambrian quartzite, carrying from 5 dwts. to 7 dwts. per ton, is crushed by rolls. The ore is fed to two 16 by 36 in. rolls used as cracking rolls and two others of the same size are used as finishing rolls. The final product goes through a ¼ in. mesh direct to the cyaniding vats. The rolls require 100 h.p. The milling and cyaniding cost is 2*s.* 2*d.* per ton and 14,800 tons of ore are treated monthly.

Ball Mills.

Krupp ball mills are used extensively in Kalgoorlie where 44 are at work. Size No. 5 will crush up to 45 tons of ore per day consuming 25 h.p. No. 8 will crush 90 tons per day requiring 50 to 60 h.p. About 45 per cent. of the product from a 25-mesh screen will pass 150-mesh. It is charged with 1 or 2 tons of steel balls and revolves from 21 to 25 times per minute. They work well on either wet or dry ores. The wear and tear of liners, hunch and scoop plates cost 4·64*d.* per ton milled.

Milling Costs.

The following are the milling costs of different stamp mills :—

Mill.	Stamps.	Tons Crushed Monthly.	Cost of Milling per ton.	Rate of Wages per day.	Remarks.
Tonopah, U.S.A.	100	15,000	12*s.*	18*s.*	Silver Gold ore
Goldfield Con., U.S.A.	140	29,500	9*s.*	18*s.*	Silver Gold ore
Ivanhoe	100	16,600	8*s.* 9*d.*	12*s.* to 14*s.*	Bromo-cyanide treatment of slimes
Oroya Brownhill	50	8,950	17*s.*	12*s.* to 14*s.*	Bromo-cyanide treatment of slimes
Gt. Boulder	—	14,800	12*s.* 4*d.*	12*s.* to 14*s.*	Dry crushing with Griffin mills. Roasting.
Melones, Cal.	100	12,000	1*s.* 1½*d.*	10*s.*	Cheap power, labour and supplies
New Unified (Rand)	—	10,000	1*s.* 4*d.*	—	Milling only
Simmer East	—	—	2*s.* 6*d.*	—	Milling only

On the Rand, cost of milling of those companies using tube mills varies from 4*s.* 10*d.* to 8*s.* 8*d.* per ton of ore.

In California, with free milling ores and cheap water power, milling costs average from 2*s.* to 4*s.* per ton. In Alaska, with large tonnages of soft, free milling ore treated daily and no cyaniding or fine grinding the costs are about 1*s.* per ton of ore.

Horse-Power per Ton of Ore Treated per Day.

Type of Mill.	Mesh.	Horse-power.
Stamps and vanners	20 to 40	0·75 to 1·0
Coarse concentration	10 to 20	0·5 to 0·8
Combination-stamp	16 to 30	1·5 to 1·75
Chloridising stamp (dry)	to 16	2·0 to 2·5
Chloridising stamp (wet)	to 40	4·0 to 4·5
Magnetic separator	—	0·25 to 0·5
Cyanidation (dry) roll-crushing	20 to 30	0·5 to 0·8
Cyanidation (wet), stamp crushing and sliming	to 80	0·75 to 1·5

(*J. A. Barr*, 'Testing for Metallurgical Processes.')

Standards Adopted by the Institution of Mining and Metallurgy.

1 oz. of fine gold = value 85*s.*
1 ton = 2,000 lbs. (avoirdupois).
1 miner's inch = a flow 1½ cubic ft. of water per minute.
1 sluice head = „ 60 „ „
1 gallon of water = 10 lbs. at 34°.

Temperatures are to be expressed in centigrade.
Screen apertures and diameters of wire are equal, giving 25 per cent. screening area.

GOLD AND SILVER TABLES.

It is the practice of Continental and South American engineers to report the values of ore in grammes per metric ton. English engineers generally employ the method of quoting values in grs. and dwts., in some cases per long ton of 2,240 lbs., in others per short ton of 2,000 lbs.

TABLE for Conversion of Grammes per Metric Ton into Grains, etc., per Long and Short Ton.

Grammes per Metric Ton.	Per Short Ton.		Per Statute Ton.		Grammes per Metric Ton.	Per Short Ton.		Per Statute Ton.	
	Dwts.	Grs.	Dwts.	Grs.		Dwts.	Grs.	Dwts.	Grs.
1	0	14	0	15·7	6	3	12	3	22

Alluvial or Placer Mining.

Deposits of auriferous or tin-bearing alluvial gravels are termed placers, alluvial drifts, or more simply alluvials. They are classified as shallow or superficial and deep-lying, sometimes called deep leads. Deep leads are accumulations of gravel from extinct or ancient rivers. They are mostly capped by igneous flows, as in California and Victoria, though sometimes they may be buried under recent gravels or drift, as at Lightning Creek, B.C., and the Lena Goldfields in Siberia.

The methods of mining used to exploit deposits of this character resemble pillar and stall in some cases and long wall in others. In California the gravel beds can be attacked by means of adits which also serve as drains for the large amount of water present. When the topography of the ground permits adits being used, the cost of mining is low, as at the Hidden Treasure, California, where the costs average 4*s*. 6*d*. per cub. yd. of gravel washed. In the Deep Leads of Victoria, where the pumping charges were unusually large (eleven million gallons per day being raised from one mine), the total cost per cub. yd. was 12*s*. to 15*s*. At the Lena Goldfields the total cost is from 20*s*. to 30*s*. per cub. yd. of gravel washed.

Superficial Deposits.—All gravel under 60 feet in thickness may be termed shallow or superficial gravels. Surface gravels are worked by the following methods:—

Panning.—A miner can pan ½ cub. yard to 1 cub. yd. of gravel per 10-hour shift, depending on character of ground and nearness to water; 100 pans per day is a good day's work. Gravel in place is usually estimated at 3,000 lbs. per cub. yd., and the standard sheet iron pan 16 ins. diam. at top and 10⅝ ins. diam. at bottom will hold 20 lbs.; 150 pans full will make a cub. yd. of dirt.

Rocker.—A man can rock ordinarily from 2 to 3 cubic yards of gravel per day, and save, in practical mining, 90 per cent. of the gold. In alluvial examinations the rocker plays a most important role, and is used in conjunction with the pan for determining the gold contents of any parcel of gravel. When used for this purpose, the design of the rocker differs slightly from that of the ordinary miner's rocker. A well-designed rocker, carefully employed, should save practically all the gold. The plans of most rockers, as published from time to time, are those of the ordinary mining rocker, which is too short, and set on too great a grade for use in saving fine gold. If much fine gold is present in the gravel, it will be advisable to use a strip of common Brussels carpet, laid along the floor of the rocker. This carpet is held in place by cleats and so can be easily removed in cleaning up.

Long Tom or short sluice can handle 3 to 10 cub. yds. of dirt per day, depending on the amount of water available and the character of the dirt.

Hand Sluicing.—Capacity of a sluice box depends upon the amount of water, grade of sluice, deposition of tailings, and character of gravel. No capacity can be given. Grade of sluice varies from 2 ins. to 21 ins. per box (12 ft.). An ordinary sluice box is made from 2-in. planks, and is 12 ins. wide by 12 ft. long.

Grade and Duty of Sluices.

Grade and Duty of Sluices.—The relation of actual width to the best ratio of quantity to width may not be very significant, but there is a notable increase in efficiency in passing from the smallest widths to the larger, and boxes less than 1 ft. wide are to be avoided, especially if the gravel is coarse. Treating 30 to 40 mesh sand on a 1 per cent. grade (say 1¼ in. per 12 ft. box), one sluice head of water requires a channel 2 ft. wide to enable it to attain maximum duty. On a 2 per cent. grade, half a sluice head requires 2 ft. of width, the quantity of water required for maximum duty with a fixed width diminishing with increasing grade, but at what rate there are insufficient data to determine. Apparently the best width required for constant quantity of water varies directly as the grade. Coarser material requires a greater depth of water, and for 4 to 6 mesh gravel on a 2 per cent. grade, 1 ft. of width per sluice head is indicated. Variations up to 50 per cent. in the water make little difference to its duty, consequently the actual position of the optimum is not easily determined. Naturally the capacity of the sluice itself is correspondingly varied, and the mode of transportation and the saving are doubtless affected in any case.

The rate at which duty varies with slope is the resultant of so many variables that no law can be stated for all cases. In the neighbourhood of the best conditions the Utah experiments support the approximate rule that duty (water, width, and material being constant) varies as the 1·75th power of the grade. A single experiment with natural gravel on low grades by the U.S. Geol. Survey gave the 1·84th power. (*R. T. Hancock.*)

Good modern practice provides about 1 ft. of sluice-box width for every 2 cub. yds. of average material treated per hour, and 3,000 gallons of water per cub. yd. treated on a grade of 6 ins. to 12 ft.

Besides the ordinary feeding of sluice box by means of hand shovelling, many modified methods of feeding and disposing of tailings are employed. In Russia and Siberia the favourite method in use is to transport the gravel to and from the sluice box (here greatly modified from the plain open sluice box) by the employment of horses and small carts. This is a most expensive system and the yardage treated is small. Other variations are: the use of wheel barrows, tramming by cars, handling gravel by means of derricks, digging gravels by means of steam shovels, and loading into cars or direct into sluice, feeding sluice by means of scrapers operated by horses or steam power (drag-line scrapers).

The methods of preventing accumulation of tailings are to deposit them in running water or to remove them by means of drags, belt or link elevators, or hydraulic elevators.

HYDRAULIC MINING.

Hydraulicing proper is the method of mining by which jets of water under high pressure are thrown against a gravel bank, thereby undermining the gravel which falls, and is carried by the current into the sluice. The necessary pressure is obtained either by natural means, i.e. by conveying the water from some source having a greater elevation than the working face, or by pumping directly into the supply pipe by powerful pumps. In the former case water is conveyed to the working by means of pipes, flumes or ditches. Ditches are generally most convenient and economical for conveying water for long distances, but sometimes the nature of the ground is such (either too porous or too rocky and difficult to excavate) that a flume becomes cheaper. When lumber is abundant wooden flumes are built, but in many cases, especially in the tropics, where wood rots rapidly, sheet steel flumes are preferable. Steel flume per foot, including rivets, angle iron, etc., ready for transport, costs from 4*s.* to 11*.*; the sizes vary from a cross-section of 1·28 sq. ft. to 20·48 sq. ft. From the ditch or flume the water is fed through a strainer into a pressure box. From here, a pipe leads to the Y's, which in turn lead to the monitors or giants.

Monitors or Giants.

Monitors or Giants.—These are appliances consisting of a base for attachment to the pipe line and a long conical reducing piece, arranged with one or more joints so that it can be rotated in any direction horizontally and through a very wide angle vertically. The smaller or conical end is fitted with a nozzle butt to which different sizes of nozzles may be attached as circumstances may require. Modern giants are fitted with deflectors, attachments on the butts whereby the giant is turned or deflected by means of the force of the water itself. The high-pressure giants also have ball-bearing joints.

Nozzles from 2 ins. up to 10 ins. are used, working under heads or pressure from 100 up to 600 ft. or more.

The amount of gravel which can be washed down will depend upon its nature, upon the volume and pressure of the stream of water issuing from the nozzle, and is also dependent in no small degree upon the skill of the operator who handles the giant.

The following gives the approximate amount of gravel washed under various heads :—

Effective Head in Feet.	Size of Nozzle.	Flow in Cub. Ft. per Minute.	Approximate amount of Gravel in 24 hours in Cub. Yds.	Weight of Giant. Lbs.	Price of Double Jointed Ball Bearing Giant.
					£
100	2 ins.	104·88	160	120	28
200		148·32	230		
300		181·61	280		
400		209·82	320		
100	4 ins.	420·06	650	225	55
200		594·00	930		
300		727·56	1,130		
400		840·12	1,300		
100	6 ins.	944·58	1,460	335	66
200		1335·72	2,000		
300		1634·08	2,540

200		2375·46	3,600		
300		2909·58	4,500		
400		3239·70	5,300		
100	10 ins.	2624	4,080	690	107
200		3711	5,760		
300		4545	7,050		
400		5248	8,140		

(*Hendry.*)

Hydraulic Monitors and Pelton Wheel Jets.

J. J. Garrard (*Trans. I.M.M.* 1917) gives a table of discharges in cubic feet per minute for different sizes of nozzles and various heads derived from the formula : Delivery in cub. ft. per min. $= 3{\cdot}75\, d^2\sqrt{P}$, where d = diameter of nozzle opening in ins. and P = gauge pressure in lbs. per sq. in., or effective head $\times 0{\cdot}4326$. An equivalent formula given by him is $2{\cdot}468\, d^2\sqrt{h}$, where h = effective head in ft. The factor 2·468 allows for a nozzle contraction coefficient of 0·94, whereas Hendry's figures in the above table are based on the theoretical value 2·624, and make no such allowance.

Costs.

The costs per cub. yd. were at North Bloomfield 2·05*d.* per cub. yd. and at La Grange 3*d.*

In British Columbia one and a half million cub. yds. were mined and washed at a working cost of 0·97*d.*

In Northern California placer ground containing only 1·26*d.* per cub. yd. has been profitably worked. The amount of gravel washed was 1,251,399 cub. yds., yielding 6,330*l.* The profit obtained was 821*l.*

Hydraulic and other Elevators.

When a hydraulic mine possesses an insufficient slope of bed rock for moving material (the lightest grade permissible being 220 ft. to the mile) other methods of disposing of the gravel 'piped' must be employed. Where water under pressure is cheap and abundant the hydraulic elevators are employed. They are of the pipe type—either Hendry, Evans or Campbell and the Giant Elevator.

The pipe elevator operates on the principle of an injector. Water under pressure is discharged through a nozzle set within a steel jacket, creating a vacuum, and causing water and sand and gravel fed into intake to rise to a height corresponding to 10 per cent. of the head under which the water is applied.

Three sizes are made : 10-inch throat 3½–4½ inch nozzle, using 300 to 500 ins. of water ; 12-inch throat 4½–5 inch nozzle, 500 to 750 ins. of water ; 15-inch throat, 750 to 1,000 ins. They weigh about a ton and cost 250*l.*

In South Oregon, U.S.A., at the Weimer placer mine, two hydraulic elevators are employed to handle the gravels. One of them has a lift of 39 ft., and operating with a head of 330 ft., uses 11 cub. ft. of water per sec., besides taking all water from two No. 2 Giants. The second elevator has a lift of 9 ft., a head of 125, and uses 18 cub. ft. of water per sec. besides all the water from the first elevator. This makes a final discharge of 40 cub. ft. per sec.

Giant Elevators.

Giant Elevators.—Besides undermining and cutting the gravel it has been discovered that gravel can be effectively 'driven' up a slope or incline to a raised line of sluices by means of the power of water under pressure. An elevator based on this principle is termed a 'stacker.'

In California a stacker was operated as follows: A chute was built sloping upwards at 30°. This was 4 ft. wide by 24 ft. long and constructed of 1½-inch planks. Riffles 2 ins. apart and with a drop of 2½ ins. between were laid across the bottom. These were covered by an iron grizzly. At the foot of this chute a 3-foot sump was dug in which was set up a hydraulic elevator with a 12-inch throat and worked by a 5-inch giant. This elevator, working under a 90-foot head, elevated to 16 ft. vertically the seepage, fine and water from two field-giants.

Twenty feet in front of the stacker was installed the 3-inch drive giant. Two 4-inch field-giants wash the gravel to the chute and the drive giant forces it up the stack, the fine material falling through the grizzly and down the riffles to the elevator, which raises it to the sluice-boxes.

The field-giants handled 600 cub. yds. per 24 hours, and the gravel could easily be raised to 25 ft. vertically by means of the drive giant. The cost of handling material exclusive of equipment was under 2½*d.* per cub. yd. (*S. S. Smith.*)

Ruble Elevator.

Ruble Elevator.—The Ruble elevator is constructed on the above principle, but it is more portable and does away with the hydraulic elevator. It is also self-contained, as the sluice-box is part of the machine.

In Idaho, U.S.A., this elevator has been tried with excellent results (*see* Porter, T.A.I.M.E., 1909, for a detailed description of this elevator). The following points are claimed to its merit: 1. It handles larger rocks with less water than other types of elevators. Handles boulders up to 1 ton in weight. 2. It dispenses with the boulder crew, either at the mine, ground, sluice-box or dump. 3. It saves the gold and the gold-saving department may be protected by lock and key. 4. The gravel is picked up in close proximity to the giants, the gold immediately extracted, and the boulders and other waste material dropped back on bedrock previously worked off, instead of being transported a long distance to the dump. It makes its own dump.

Mechanical Elevator.

Mechanical Elevator.—In regions where water is neither cheap nor abundant, in handling gravel or tailings, resort must be made to some form of mechanical elevators. A mechanical elevator was erected some years ago on Bonanza Creek, Alaska. This was made of a frame of steel, 49 ft. high, mounted on wheels. The gravel was elevated by a bucket line of the close-connected type, 76 buckets in all, each with a capacity of 3 cub. ft. each. These discharged at a rate of 26 per min. directly into a sluice-box. The pit was drained by means of a 12-inch centrifugal pump, assisted by a hydraulic jet. The power was 200 h.p. in all, 35 for the bucket line and 165–175 for the pumps. The actual capacity per day was 1,500 yds. (*T. A. Rickard*). The first cost of this machine was high, and in actual running it proved costly in operation and repairs. Another machine of the same type, but employing a heavy dredge bucket, is being erected in Eastern Canada. No results of actual working are yet to hand.

Centrifugal Pumps.

Centrifugal Pumps as a means of elevating gravel and tailings have been extensively employed in Australia. It is claimed that with wood fuel at 7*s.* per ton of 50 cub. ft. and European rate of wages paid, to elevate tailings with pumps should not cost more than 2½*d.* per cub. yd. of solid. Thompson & Co., of Victoria, are the makers of gravel pumps suitable for this class of work. Their pumps vary in size from 3½ ins. to 16 ins. The capacity of solids per hour from 7 to 150 cub. yds. The indicated horse-power from 2½ to 583. The combined suction and delivery head from 10 feet to 100. An installation of this kind possesses the advantage of being cheaper to erect and easier to move than the belt or bucket type of elevators mentioned. However, where there is an undue amount of large stones present in the gravel, the latter type is preferable.

Dredging.

The most important form of alluvial mining is dredging. In 1913 there were 70 dredges at work in California alone, 55 in Russia and Siberia, and 30 in New Zealand. When all conditions requisite for successful working are present, when the ground has been properly proved and well designed and effective dredge installed, then this type of mining is the safest and surest of all forms of mining investment.

Dredging properties call for certain conditions, and unless these exist the success of the enterprise suffers. The conditions are: 1. The presence of gold, which should be evenly distributed throughout the gravels. 2. Sufficient gravel to warrant the installation of at least one dredge. 3. Soft even bedrock. 4. Absence of boulders. 5. Absence of permanently frozen ground. 6. Absence of great amount of clay. 7. Absence of floods. 8. Surface should be of an even contour—not rough and broken. 9. The ground should retain sufficient water to float dredge (50 miner's ins.). 10. The economic conditions, i.e. labour, transport, climate, vary inversely with amount of gold in gravel.

Broad flood plains or ancient lake gravels form more suitable dredging ground than does deposit, situated in narrow rocky gulches. Frozen ground cannot be dredged without preliminary thawing. Dredging of gravels lying in rapid rivers is risky as there is always danger of losing the dredge by sudden floods. Gravels from 10 ft. to those 60 ft. below water and 20 ft. above have been successfully dredged.

The modern gold dredge consists of a hull or pontoon of wood or steel upon which is mounted the digging device, a line of buckets capable of being raised or lowered; the washing plant; the gold-saving tables; the stacker or elevator which disposes of the tailings, the sand-pump and the motors or engines. The dredge digs the gravel, washes it, extracts the gold and disposes of it in the form of tailings. It digs its own pit. Suction dredges are used at times. There are two types of bucket dredges, the New Zealand and the American type. The latter has been evolved from the New Zealand dredge to suit conditions existing at Oroville, and it now forms a distinct type and is used on all properties controlled by American capital.

Both types have their advocates and both their utility.

Briefly, the New Zealand type of dredge is a lightly constructed, light-powered boat of steel pontoons, with open connected buckets, and employs a headline in digging. Its first cost is low, its capacity small, and it is better adapted to work in ground of a loose, easy-digging nature. It is too lightly built for heavy ground.

The Californian or American dredge is costly, very heavily built, with close-connected buckets, digs with spuds, and till lately built with wooden hulls.

For properties where the transport is high, as in parts of Siberia, and where heavy repairs are difficult, a well-built New Zealand type of dredge, with ample stock of spares, is preferable. Indeed, its choice is imperative in some cases, for the high transport costs to some properties exclude the use of the ponderous American type of dredge. On the other hand, cheap transport, access to machine shops, and with heavy or stiff semi-cemented gravel, or large deep deposit of fair digging gravel (the latter permitting the handling of enormous daily yardages) are conditions favourable to the use of the American dredge.

The following figures relate to both the Californian and New Zealand types of dredge. In the former case the dredges quoted are of the Standard American type, i.e. built with wooden hulls, the stacker of the rubber-belt type and the dredges electrical equipped throughout. The cost includes erection in America. The yardages given, while estimated, have been actually accomplished in Oroville ground.

CALIFORNIAN TYPE.

Size of Buckets.	Estimated capacity per month. In cub. yds.	Digging Depth below Water Line.	Weight exclusive of Hull.	Price Erected.	Horse Power.
Cub. Ft.		Ft.	Tons.	£	
3	45,000– 60,000	36	350	12,000	180
5	90,000–110,000	36	520	16,000	220
7	110,000–150,000	35	576	19,000	300
8½	150,000–185,000	48	1,000	36,000	560*
13	250,000–280,000	40	1,100	50,000	415

* This includes 100 h.p. for pump for two monitors or giants.

In the following figures of New Zealand type the dredges referred to are built in England, and the price is f.o.b. London. The weights include steel hull. The capacities are over-estimated in this case, as the yardage given has never been accomplished in actual practice. For actual capacity the yardages quoted should be reduced from 25 per cent. to 50 per cent. according to conditions of ground.

In Siberia the following yardages were realised by this type during a season of seven months : 4½ ft. dredge, 165,100 cub. yards ; 5 ft. dredge, 190,500 cub. yds. ; 6 ft. dredge, 228,600 cub. yds. ; 7 ft. dredge, 254,000 cub. yds.

These dredgers are equipped with an open connected bucket line and a pan stacker, except the first, which has no elevator but discharges from a sluice in the rear. They are all steam driven.

NEW ZEALAND TYPE.

Size of Buckets.	Estimated Capacity. In cub. yds.	Digging Depth below Water Line.	Weight including Hull.	Price, f.o.b. London.	Horse Power.
Cub. Ft.		Ft.	Tons.	£	
3	30,000	20	100	3,000	35
4	40,000	20	180	7,000	—
5	50,000	26	220	8,000	56
6	60,000	40	280	9,100	—
7	74,000	32	350	11,500	180
3½	—	20	235	4,400	50
5	—	20	250	4,625	60

Note.—The figures for two last dredges are for machinery only. The hulls of these were of wood.

Cost of Dredging.

The Cost of Dredging depends on the character of the ground, the climate, transport, labour, power, yardage treated, make of the dredges, and the personal equation of the management. It varies greatly. In countries where seasons are short and labour and supplies high, i.e. in the Far North, Alaska and Siberia, the costs are highest. In Alaska 2,300,000 cub. yds. were dredged at a cost of 1*s.* 4*d.* per cub. yd. This included thawing charge amounting to 7½*d.* per cub. yd. In Siberia the cost with one 5-ft. open connected dredge averages about 6*d.* per cub. yd.

In California a dredge having 3½ ft. bucket digging in ordinary loose gravel and sand had an average working cost for six years of 3·9*d.* per cub. yd. The new 16-ft. cub. ft. dredge in California, handling 300,000 cub. yds. a month, is working at a cost of 1*d.* per cub. yd.

DATA ON OPERATION OF CALIFORNIAN DREDGES.

Capacity of Buckets.	Period of Observation.	Actual Operating Time.	Gravel Dug per month.	Depth of Gravel.	Cost per cub. yd.	Character of Ground.
Cub. Ft.	Months.	Per Cent.	Cub. Yds.	Ft.		
3	12	82·3	38,200	27	3·50*d.*	Favourable
3½	12	83·7	38,400	35	3·66*d.*	Compact
5	12	—	67,600	36	3·32*d.*	Medium
7	12	79·0	84,700	28	2·20*d.*	Compact
7½	12	73·2	113,900	70	2·08*d.*	Medium
8	6	72·2	97,000	42	1·96*d.*	Light
13½	8	77·7	225,000	19	1·15*d.*	Fine and light

At Waipoi, New Zealand, 212,000 cub. yds. of soft ground were handled in 45 weeks at a cost of 3·3½*d.* per cub. yd.

In Victoria, during 2,006 weeks 14,927,269 cub. yds. of material were handled by 50 dredges at a cost of 2·67*d.*

Thirteen dredges operating in California for the Natomas Consolidated in 1914 handled 25,850,000 cub. yds. at a total cost of 5·8 cents per yd. Of these one handled nearly 2,000,000 at 2·5 cents and another over 2,000,000 at 7·14 cents. Ten dredges of the Yuba Consolidated operating in California in the same year handled 17,000,000 cub. yds. at a cost of 4·40 cents per cub. yd., varying from 3·29 to 6·86 cents. The Conrey Company in Montana, between 1906 and 1915, treated 32,000,000 cub. yds. at 5·91 cents, the cost ranging from 9·79 cents in 1906 to 5·99 cents in 1915. The gradual reduction in total costs was mainly due to the increasing yardage as larger and more powerful dredges were installed, the increased yardage lowering the indirect or overhead charges. Direct operating charges did not vary much, averaging 5·91 cents. The dredges of a company operating in Colorado handled in 1914 3,000,000 cub. yds., at 5·9 cents. One dredge in Idaho in 1914 handled 4,670,000 cub. yds.—a world's record—at a total cost of 2·77 cents per cub. yd. In Colombia, South America, the Pato dredge in 1914 handled 920,000 cub. yds. at an operating cost of 18·4 cents and a total cost of 23·2 cents per cubic yard. This was an 8-ft. bucket dredge. The 5-ft. Gumaos dredge in the Philippines handled 1,850,000 cub. yds. in twenty-seven months at a cost of about 12 cents per cub. yd. In Alaska in 1917 seven dredges of the Yukon Gold Co. operated 151 days at Dawson, handling 4,583,326 cub. yds. at an average cost of 25·81 cents per cub. yd. Sixty-five acres, or 60 per cent. of the ground, was frozen and required thawing by steam. At Idatarod the company's dredges operated 192 days, handling 871,045 cub. yds., at 48·1 cents. The company's five dredges in California handled 6,161,941 cub. yds. at an average cost of 3·71 cents per cub. yd. Hydraulicing operations treated 2,143,444 cub. yds. at 11·8 cents, the duty of the water being 4·18 cub. yds. per miner's inch.

SECTION XXXVII

PART II

MINERAL VALUATION.

(By Professor Henry Louis, M.A., D.Sc., A.R.S.M., M.Inst.C.E., etc.)

General Principles.

Under the head of Mineral Valuation are included two somewhat different valuations, namely, that of a mineral property, whether worked or not, and that of a mine as a going concern ; the difference arises from the fact that the proprietor of the minerals does not as a rule work them himself, but disposes of them, usually for a royalty, to the mine-owner who works them. In cases where the mine-owner is also the proprietor of the minerals, it is generally more convenient to value the mine, the royalty derivable from the ownership of the minerals being included as a part of the profit derivable from the mining operations.

In either case it is necessary to determine the present value of a number of annuities, the latter being the annual revenue derived from the royalties or the profits, as the case may be.

The amount of the royalty per ton is generally known or can be closely approximated, being the price paid or to be paid for the mineral in its unsevered condition as it lies in the deposit.

The profit per ton must be estimated from the probable cost of working and the probable value of the mineral in its marketable condition.

The tonnage to be wrought annually must be estimated, having due regard to all the conditions of the deposit, and should be taken to be the amount that can be extracted, so as to produce the maximum total profit over the period under consideration. It is obvious that a deposit worked out with excessive rapidity will yield no profit when the interest on the capital outlay required to so work it exceeds the profit derivable from working ; on the other hand, if worked excessively slowly, the standing charges may exceed such profit. Between these extremes lies the rate of economic working ; it will generally be found that there is a considerable range of working rate, within which the economic results are practically uniform, and the best rate within that range is usually determined by market conditions or other purely commercial considerations.

The probable total quantity of mineral that can be economically produced from the property must next be calculated, meaning thereby the amount which is as likely to be exceeded as to be fallen short of ; it is obvious that the quantity that can actually be produced from any property can never be known until the property has been exhausted, when the information is naturally valueless. Hence the question becomes one of probabilities, never one of actually ascertained figures, and must always be considered as subject to the laws of probability in the mathematical sense. The quantity thus estimated divided by the estimated or proposed annual output determines the probable life of the property ; if the latter is held under mineral lease, the period of which is less than the probable life, the length of the lease is substituted for the probable life in the calculations.

Sometimes not only the tonnage but also the assay value of the mineral deposit enters into the calculation, and in either case it is never a certainly known figure, but always the most probable figure, that has to be employed. Thus, where the value of a mineral deposit depends upon its thickness and its assay value, let the ascertained most probable thickness be T units and the ascertained most probable value be V units ; as neither are known with certainty, these figures should be written $T \pm t$ and $V \pm v$ respectively, where t and v are the respective probable errors ; then since the probable error of the product VT is $\sqrt{T^2v^2 + V^2t^2}$, the value of the deposit will be a function of $VT \pm \sqrt{T^2v^2 + V^2t^2}$. (See *Mineral Valuation*, by H. Louis, p. 128.)

In the following formulas, the annual income = annual tonnage × royalty per ton, or annual tonnage × profit per ton, as the case may be, will be designated by a.

The number of years of life of the property or of the lease will be designated by n.

The problem then becomes that of determining in the first instance the present value (P) of a series of annuities of £a for a term of n years.

Generally the ordinary compound interest formulas apply, which show that X pounds invested at a rate of interest i per unit will amount in n years to $X(1+i)^n$, and conversely the present value of Y pounds payable at the end of n years, allowing interest at rate i, is

$$\frac{Y}{(1+i)^n}.$$

(See page 3.)

The main difficulty in all mineral valuations lies in determining the proper rate of interest to allow. The rate of interest in operations in which there is practically no risk, that is to say where the probability of the payment of capital and interest in full is practically unity, may be taken to be the rate obtainable by investment in such securities as Trustee Stocks. In all mining operations the risk is always greater, or in other words the probability of payment is less, hence a higher rate of interest is demanded to cover the risk. If i be the safe rate of interest the risk rate may be expressed by ri, where r is a number greater than unity, depending upon the conditions of the case, and which may conveniently be described as the risk factor; it may also be defined as the reciprocal of the fraction representing the probability of success, and is therefore greater the more hazardous the nature of the enterprise. In practice the risk factor ranges from 2 to 5, being lowest in well-proved bedded deposits, the uniformity of which has been determined by experience, and highest in veins or masses in which values are known to be very irregularly distributed. It is less where money is invested merely in the purchase of a mineral property than when it is invested in a mining enterprise, because royalties form a first charge on revenue and are almost invariably secured on the assets of the mining enterprise, whereas the latter can take only remainder profits, which are totally unsecured.

The determination of a proper risk factor is the principal problem that the mining engineer has to solve in valuations.

Present Value.

Let $ri=s$, so that s is the rate of interest *per unit* that is required in any given case.

Some writers call i the 'accumulative' and s the 'remunerative' rate of interest; the term 'risk rate' will be adhered to here in order to emphasise that the high rate is required in compensation for the risk that the investor runs. Of course i is governed by the money market, and is the rate of interest paid on investments in Government stocks and similar first-class securities; it will be noted that s varies directly with i.

The value of the mineral property or mine *at the moment of commencing profitable operations* is therefore P, the present value of n annuities of £a. This should obviously be equal to the present value of sums of £a payable at the end of each of the first, second, third, etc., years up to the end of the nth year, and this sum

$$=\frac{a}{s}\left(1-\frac{1}{(1+s)^n}\right).$$

It is sometimes useful to remember that, if A is the present value of £a due at the end of n years,

$$P=\frac{a-A}{s}.$$

The expression for present value given above is often spoken of as Inwood's formula. Calculations are easily made by this formula; the table on page 6, which gives the present value of an annuity payable at the end of each year for a varying number of years and at various rates of interest, obviates this calculation, as it is only necessary to multiply the present value taken from the table by the amount of the annuity. The table gives the values of

$$\frac{(1+s)^n-1}{s(1+s)^n}$$

for different values of n and s; in the headings of the table the rates of interest are given per cent. and not per unit. Again, the sum of n annuities of £a payable at the end of each year up to the end of the nth year is

$$\frac{a}{s}\left((1+s)^n-1\right),$$

and the present value of this sum is

$$\frac{a}{s}\cdot\frac{(1+s)^n-1}{(1+s)^n}$$

as before. Again, the annuity may be looked upon as part interest on the present value, the remainder being applied annually to the reduction of the capital, interest being paid each year on the unredeemed portion of the capital. If calculated on this basis the same result is obtained.

There is yet another method of looking at the problem. The annuity exceeds the simple interest on the present value by an amount equal to $a-Ps$ in each year; if this difference be allowed to accumulate at rate s for n years it will amount to

$$\frac{a}{s}\cdot\frac{(1+s)^n-1}{(1+s)^n}=P,$$

that is to say, to the original capital, as it obviously should do, because the purchaser of an annuity, spending each year only the interest on the capital invested, should get back his capital at the end of the period, because this operation would be equivalent to investing the capital at the given rate of interest during the given term of years.

This last method of looking at annuities has given rise to another method of calculating them, known from its originator as Hoskold's method. He considers that the risk rate of interest s should be allowed upon the capital, but that the difference between the annuity and the interest $(a-Ps)$ should be looked upon as accumulating at a safe rate i because it is not necessarily invested in the risky mining operation. This view gives rise to the formula

$$P=\frac{a}{\frac{i}{(1+i)^n-1}+s}.$$

This value may be taken out from any ordinary tables as follows :—

$$\frac{(1+i)^n-1}{i}$$

is the amount of £1 at interest i for n years, and the reciprocal

$$\frac{i}{(1+i)^n-1}$$

is the sinking fund for the repayment of £1, i.e. the sum to be set aside annually and allowed to accumulate at interest i in order to amount to £1 in n years. These values are obtained from tables (see pp. 3 and 9). The denominator of the fraction in Hoskold's formula can be taken out by adding the risk rate to the sinking fund for £1 at interest i for n years.

This method is often used, but is not one that fairly answers all the tests of a true annuity formula. Nevertheless, it is used by valuers on the grounds that the difference between the annuity and the simple interest cannot, in fact, be invested at the risk rate s, but must be invested at the safe rate i, and that this method, therefore, more correctly represents what would obtain in actual practice.

Hoskold's method depends upon considering only one out of the various methods in which the true annuity formula may be looked at; obviously the two can be made to give the same result by selecting suitable risk factors in each case. Thus if r is the risk factor in Inwood's formula, and r' in Hoskold's method, the present values will be the same whichever formula be used, when

$$r'=\frac{r(1+ri)^n}{(1+ri)^n-1}-\frac{1}{(1+i)^n-1}.$$

It follows that r' must be greater than r; in other words Hoskold's method allows a rate of interest higher than the stipulated risk rate, and hence puts a lower present value on a given annuity. It need hardly be said that both his method and the ordinary method provide equally for the replacement of the original capital, if suitable sums are set aside in each case out of the annuities received.

Increasing and Decreasing Values.

The above methods of valuing mineral properties tacitly assume that the mine will forthwith commence to produce at its full rate of output and will continue to do so until the mineral is worked out; this is, of course, not the case in practice, a mine only reaching its full output after several years, and this gradually declining again as the deposit approaches exhaustion. There would be no difficulty in allowing for this in the valuation, but as a rule it is neglected; as has already been pointed out, the figures on which the valuation is based are only probable, not actual figures, so that there is no use in endeavouring to attain minute accuracy in these computations.

There is obviously no difficulty in introducing these refinements if it is considered desirable; the computation is made as above for the estimated period of full production deferred during the period of production at a lower rate than the full output; the income expected in each year of output less than full output is calculated and its present value is determined, and all these present values are added together to obtain the total present value of the property.

If preferred, calculations can also be made directly, whether the annuity increase or decrease in arithmetical or in geometrical ratio. Let c be the income in the first year and let it increase or decrease by b each year, so that the income for the second year is $c \pm b$, for the third year $c \pm 2b$, etc., during n years. Then the present value of this annuity on the Inwood method is :—

$$c\left(\frac{(1+s)^n-1}{(1+s)^n s}\right) \pm \frac{b}{s}\left(\frac{(1+s)^{n-1}-1}{(1+s)^{n-1}s}\right) \mp \left(\frac{(n-1)b}{s} \cdot \frac{1}{(1+s)^n}\right).$$

These values can be taken out from the tables: the first expression is, as before, the present value of £c for n years at rate s; the second is the present value of £$\frac{b}{s}$ for $(n-1)$ years at rate s, and the third is the principal which will amount to £$\frac{(n-1)b}{s}$ in n years at rate s. (See Present Value Table, p. 11.)

If Hoskold's method be used, the present value is :—

$$\frac{c+\frac{b}{i}}{\frac{i}{(1+i)^n-1}+s} \mp \frac{nb}{i-s+s(1+i)^n}.$$

The first part of this expression is the present value of an annuity of £$\left(c+\frac{b}{i}\right)$ calculated for n years by Hoskold's method; in the second expression $s(1+i)^n$ is the amount of £s at interest i for n years (see table, p. 3).

Again, let c be the income for the first year and let it increase geometrically by a ratio k, so that the income for the second year is ck, for the third ck^2 . . . etc.. during n years. Then the present value of the annuity on Inwood's method is

$$\frac{c}{(1+i)^n} \cdot \frac{k^n-(1+i)^n}{k-(1+i)}, \text{ or, if } \frac{k}{1+i} = f, \text{ it is } \frac{c}{1+i} \cdot \frac{f^n-1}{f-1}.$$

On Hoskold's method the present value becomes :

$$c \cdot \frac{(1+i)^n-k}{1+i-k} \cdot \frac{i}{i+s[(1+i)^n-1]}.$$

All the above calculations are based upon the hypothesis that the annuity is paid at the end of each year; in practice royalties are mostly paid quarterly, and mining dividends at least half-yearly. To meet this point, for n substitute $2n$, and for s substitute $\frac{s}{2}$ when payments are made half-yearly, these becoming $4n$ and $\frac{s}{4}$ respectively when payments are made quarterly.

Dead-rent.

In computing the present value of mineral royalties 'certain rent' or 'dead-rent' has sometimes to be taken into account. Mineral leases usually stipulate for a definite dead-rent, which may be in addition to the variable royalty, or may be a merging dead-rent, that is to say that the amount of royalty to be paid is determined by the tonnage which is in excess of that which corresponds to the dead-rent at the agreed royalty rate. As the dead-rent is payable in full, whatever the results of the mining operations, its present value must be calculated not on the mining risk rate of interest, but on a rate obtained by multiplying the standard safe rate by a factor depending only on the financial stability of the lessee. This consideration may be neglected when the dead-rent is very small compared with the expected annual royalty, but must be taken into account when it is considerable, the present value of the whole royalty, in the case of an additive dead-rent, or of the excess of royalty, in the case of a merging dead-rent, being computed as above and added to the present value of the dead-rent.

Relinquishment.

When, as is often the case, the lessee has power to relinquish the lease after a given number of years or at stated intervals, there is a risk that the lease may be cancelled because the mine proves unprofitable or because the deposit is exhausted, and the rate of interest applicable to the

dead-rent during the definitely fixed period is estimated as above, but it must be multiplied by a risk factor representing the probability of such relinquishment in computing the present value of the dead-rent during the successive periods. Here, again, the difficulty of the problem consists entirely in determining the proper probability factor.

Deferment.

In opening a mine there is always a period of development during which no mineral is produced, or at any rate none is produced profitably, whilst the main capital expenditure in the way of shafts, adits, plant, machinery, etc., is incurred. The present value at the commencement of the profit-producing period as found above must therefore be looked upon as deferred for the requisite number of years and the actual value determined. If V be the actual value at the commencement of mining operations and d the number of years occupied in development,

$$V = \frac{P}{(1+s)^d}.$$

The risk rate of interest must be taken, because the capital is being spent and is subject to the full risks of the mining operation.

The annuity formula and deferred value formula may be combined, thus :—

$$V = \frac{a}{s} \cdot \frac{(1+s)^n - 1}{(1+s)^{(n+d)}}.$$

It is, however, better as a rule to make the computation in the two stages, as above.

The table on page 11 facilitates calculation of actual values; it gives the present value of 1*l.* due at the end of a varying number of years at varying rates of interest; the present value taken from the table and multiplied by P gives the value of V. This table gives the values of

$$\frac{1}{(1+s)^d}$$

for different values of d and s, rates of interest being expressed in the headings as percentage rates.

Mr. O'Donahue has proposed a method of calculating deferments that has some analogy with Hoskold's method of computing the present values of annuities, being also a two-rate method. He considers that simple interest at the risk rate s should be allowed on the actual value V, whilst the interest assumed to fall due accumulates at the safe rate i, whence

$$V = \frac{P}{1 + \frac{s}{i}\left[(1+i)^d - 1\right]}.$$

Since interest is never in fact paid nor payable on the actual value, this method cannot be recommended. This formula and the ordinary deferment formula may be connected as follows :— Let r be the risk factor in the ordinary method and r' the risk factor when O'Donahue's method of deferment is employed; then

$$r' = \frac{(1+ir)^d - 1}{(1+i)^d - 1} \text{ and } r = \frac{\sqrt{1 + r'i[(1+i)^d - 1]} - 1}{i}.$$

In some cases, however, where two different rates are involved, another method must be adopted. In the most general case, it is required to determine the present value, V, of a mine that will take d years to develop, during which time no profits are earned, and which will then yield a profit of £a per annum during n years, it being a condition that the original capital shall bear interest at the risk rate s, but that all accumulations can only be invested at the ordinary investment rate i. At the end of the n years the investor is entitled to receive back his capital plus the accumulations of interest (Vs per annum) at the rate i or

$$V + Vs\,\frac{(1+i)^{n+d} - 1}{i}.$$

This must be equal to the amount of an annuity of a per annum for n years, or

$$\frac{a}{2}\left[(1+i)^n - 1\right].$$

Equating :—

$$V = \frac{a\left[(1+i)^n - 1\right]}{i + s\left[(1+i)^{n+d} - 1\right]}$$

This is the same result as follows from the method of calculating deferred annuities, published by Mr. George King in his 'Theory of Finance.' Further, if $d = 0$, the above formula becomes the ordinary Hoskold formula given above.

Capital Expenditure.

From the present value, V, as determined by any of the above methods, the capital necessary to bring the mine into full work must be deducted in order to obtain the value of the mineral property ; if the capital expenditure is spread over several years, the present value of this deferred expenditure must be computed at the ordinary investment rate i, and the sum thus found deducted from V.

Deferred Development.

It occasionally happens that the valuation is required of a mineral property which it is not intended to commence to develop for a number of years ; in this case the present value must be calculated as the present value of a sum V, the payment of which is deferred for the given period at a rate of interest i per unit. The risk rate of interest must not be taken into account, because there is no mining and therefore no mining risk. If the value of V has been properly determined, making all due allowance for mining risks, the problem resolves itself into determining what capital sum must be invested in safe securities in order to produce the sum V at the time when mining operations are to be commenced. Special attention is drawn to this point, because mistakes are often made in confusing the rate of interest required during the development period and the rate required during the period preceding development, the latter depending on ordinary acutarial considerations and not on the risks incidental to mining.

Investment Value.

Finally, in comparing investments in mines or in mineral properties with other investments of capital, the effect of Income Tax as well as of Mineral Rights and Increment Value Duties must be taken into account. Mines and minerals both constitute wasting assets, but income tax is charged upon the gross revenue derived therefrom, hence not only on the true revenue, but also on that portion of the gross revenue that ought to be looked upon as forming a sinking fund set aside to replace the original capital at the end of operations ; mineral rights duties specifically affect only mineral properties and thus constitute an additional charge upon these. In both these respects, therefore, these investments are at a disadvantage compared with ordinary investments, a fact that requires due consideration in computing mineral valuations as a basis for the investment of capital.

FURNACES.

CLASSIFICATION OF FURNACES.

FURNACES IN WHICH THE CHARGE AND THE FUEL ARE INTERMINGLED.

1. Hearth Furnaces.

(*a*) With blast. Forge for smithing. Grate for zinc-white manufacture.

(*b*) Without blast. Heap and stall for coking and roasting. Trough for liquation and drossing.

2. Shaft Furnaces.

(*a*) With forced draught. Blast furnaces for smelting ores of iron, copper, lead, etc. (see p. 2494). Cupolas for iron-foundry practice (see p. 2508).

(*b*) With induced draught. Only rarely employed.

(*c*) With natural draught. Furnaces for smelting readily fusible ores. Kilns for calcining, roasting, etc.

FURNACES IN WHICH THE CHARGE AND THE FUEL ARE SEPARATE.

1. Reverberatory Furnaces (Radiation).

(*a*) With forced draught. Furnaces for the refining of metals and the smelting of ores.

(*b*) With natural draught. Furnaces for the roasting of ores. Furnaces for the manufacture of wrought iron, etc.

2. Crucible, Retort, Muffle, etc., Furnaces (Conduction).

(*a*) With solid, liquid or gaseous fuel (see p. 2511).

With electricity (see p. 2514).

Furnaces in which the Charge Supplies its own Fuel.

(*a*) Preheated furnaces with solid charge. Kilns for ore-roasting. Beehive coke ovens.
(*b*) Preheated furnaces with liquid charge. Converters for refining, etc.
(*c*) Non-preheated furnaces with solid fuel. Blast-roasting furnaces with up and down draught.

Electric Furnaces Heated by Resistance Effects.

(*a*) The charge is included in the electric circuit. Héroult aluminium furnace. Kjellin induction furnace (see p. 2514).
(*b*) The charge is heated by means of an electrically-heated conductor (see p. 2514).

Electric Furnaces Heated by Arc Effects.

(*a*) Direct heating. The charge forms one or both poles of an electric arc (see p. 2514).
(*b*) Indirect heating. The charge is enclosed in a space heated by an electric arc (see p. 2514).

Electric Furnaces Heated by Combined Resistance and Arc Effects.

Girod, Greaves-Etchells, Héroult, etc., steel furnaces (see p. 2514).

SHAFT FURNACES.

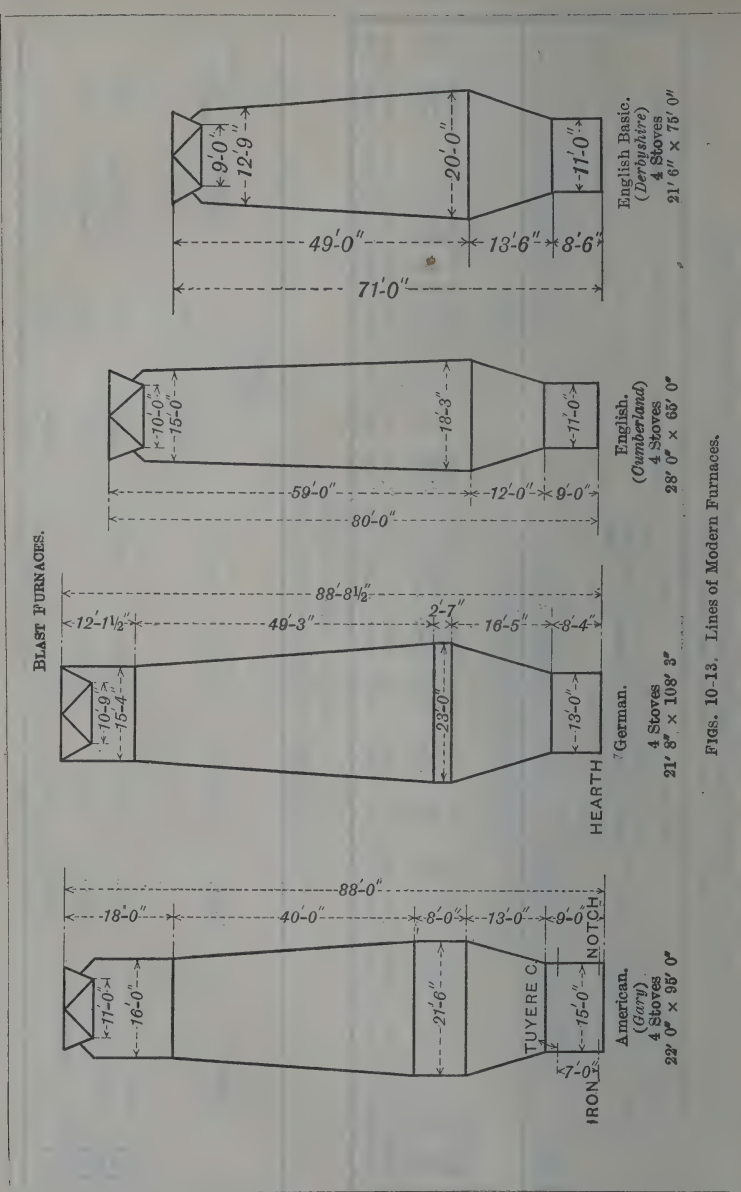

FIGS. 10-13. Lines of Modern Furnaces.

BLAST-FURNACE MATERIALS AND PRODUCTS.

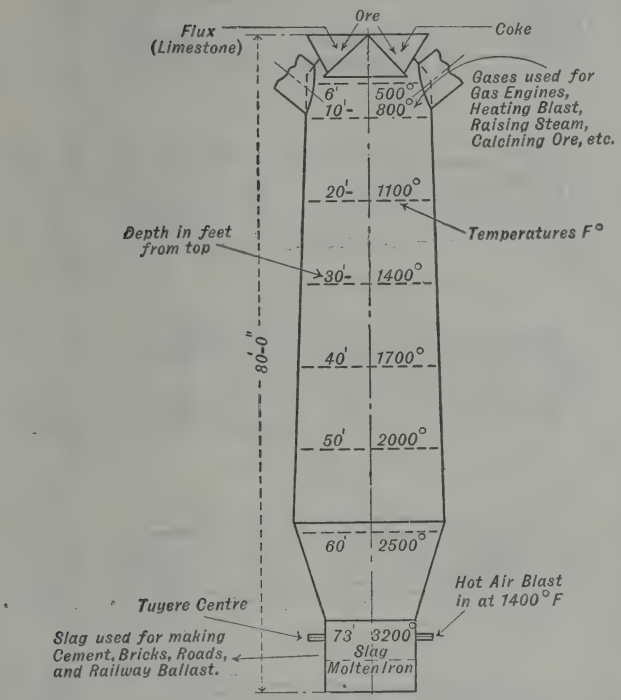

FIG. 14.

A blast furnace should be designed to suit the materials used in smelting; successful designs can best be accomplished by keeping in view the best practice with particular materials. No general formula for the design of all blast furnaces, for a given output, is possible. The following points are common to all successful blast furnace plants, and should be kept in view, in new construction:—

The aim of all blast-furnace work is the production of a good marketable iron at the lowest cost. Low costs rest chiefly on low fuel consumption; low fuel consumption is governed by the quantity of fuel, dryness and temperature of blast, with correct furnace lines for the ores smelted.

Blast temperature is entirely one of stove capacity; it is essential that stove capacity should be on the generous side.

Output will depend on capacity of furnace, diameter of hearth, and will vary according to materials used, quantity and pressure of blast, dry or wet blast, temperature of blast; blast pressure should be able easily to penetrate to centre of furnace.

Bosh line angles are found to vary very little; short steep bosh lines are a decided advantage with most materials. Leading American blast-furnacemen attribute some of their remarkable results, in part, to low steep boshes and large hearths.

Furnaces with hearths 20′ 9″ in diameter are in successful operation.

TABLE V.—SCHEDULE OF BLAST-FURNACE DATA.—*British Practice, January* 1920.

	DATA:	Frodingham Iron and Steel Co., No. 1 Furnace.	Staveley Coal and Iron Co., Ltd., Devonshire Works, No. 1 Furnace.	Dorman, Long & Co., Ltd.	North-Eastern Steel Co.	Guest, Keen & Nettlefold, Dowlais, No. 4 Furnace.
	Description of Furnace.					
1	Internal Lines of Furnace.					2	Charging gear . .	Double bell. Hopper revolved whilst charging.	Single bell. Double hoppers above sealed with flat plates.	Single bell. Hand-charged.	Single bell. Hand-charged.	Hand-barrow charged

3	Method of bosh cooling	Bosh jacket sprayed with water. Above tuyeres copper plate coolers inserted into bosh walls.	Sahlin patent water-cooled spiral bosh, thin lined interior.	Three rows of bronze coolers in open cast-iron boxes.	Steel plate bosh, thin lined, water-sprayed exterior.	Copper bosh plate coolers.

(*Forsythe.*)

In general practice, furnace shafts should have a batter of at least 0·625 in. in 12 ins.; where fine ores are smelted this could be considerably increased with advantage. Diameter of bell should be 4 ft. to 4 ft. 6 ins. smaller than diameter of throat.

The furnace should be entirely enclosed in a strong steel shell, from the hearth level up.

All parts of furnace top work should be securely fixed to main shell structure.

In designing blast-furnace details the main considerations should be (1) efficiency, (2) strength, (3) simplicity.

The number of gas offtakes should be such that the gas leaves furnace as slowly as possible, so as to avoid carrying dust over to flues.

The height of furnace varies from 80 to 100 feet; with the materials used, each district has come to fix the height found most suitable for its particular conditions.

Sufficient relief area, by bleeders or explosion doors, should be provided on top of furnace to prevent injury from slips; the relief should, if possible, be directly upwards.

For hearth well and bosbing nothing but the best quality of fire-brick should be used. The bricks should not be too large, so that they may be thoroughly burned.

For the upper lining a fire-brick with more wear resisting qualities can be used.

Care should be taken that all bricks when laid are properly bedded and tight built, with fire-clay joints as thin as possible.

In relining a furnace, the bear in old hearth need not be removed, but simply levelled to start building well on.

This will save much hard work and expense—experience will prove that nothing better for a hearth can be put in.

Some means should be taken to preserve the upper lines of furnace from wear where stock from bell strikes brickwork; a satisfactory way of doing this is to insert with brickwork alternate layers of cast iron or steel plates. In normal working, the stock level should be kept just high enough to allow bell to swing freely when full open.

The number of tuyeres is not so important (if sufficient area for output is provided) as equal distribution and penetrative power of blast.

There should always be a reserve of blowing power available after providing for normal maximum requirements.

Where blast-furnace gas is fully utilised and gas economy a necessity, the blowing should be done by gas engines. Where there is a surplus of gas the turbo-blower can be installed with advantage, and will prove an ideal blowing engine. Reciprocating steam-blowing engines are still being installed, but only in cases where conditions make it unsuitable or inconvenient to discard existing plant.

Cooling.—Apart from tuyeres, jumbos, and hearthcooling, any cooling appliances provided for the bosh or upper lining should be carefully considered; external or spray-cooling has the great advantage that leakage of water into the furnace is prevented, or rather more easily detected. The trouble caused by water leakage from blocks inserted in the building is considerable, and can never be fully known; it is often when the damage is done the leak is located. The latest practice is to spray-cool the bosh and sometimes the entire outside shell; by this means a much thinner brickwork can be used, the furnace preserves its original lines longer, and the lining has a longer life.

Stoves.—Should be as simple in design and equipment as possible, with ample facilities for cleaning and inspection, and have a good chimney draught.

Using unwashed gas, chequers should not have less than 9-in. by 9-in. openings; with washed gas smaller chequer openings can be used, giving greatly increased heating surface for same size of shell, and higher blast temperatures and lower chimney temperatures for same gas consumption. Openings 3½ ins. × 3½ ins. with 2-in. thick walls have proved satisfactory in practice.

In latest practice for heating stoves the gas and air is forced by special fan into combustion chamber, the stove burns more gas, which gives higher and more regular temperatures, with a saving up to 25 per cent. in stove construction for a given production.

Preheating the blast before entering the stove proper is in successful operation with increased average temperatures.

It is decided economy to clean blast-furnace gas, as better results are obtained.

It is no advantage to go beyond 1,550°F. in stove heats, any fuel economy being more than off-set by stove repairs.

Better results with certain ores will sometimes be obtained by running on lower blast heats; this may seem to conflict with theory, but in blast-furnace work it is often the case that sound theory follows successful practice.

Uniform ore mixtures and quality of fuel and flux should be kept in view, rather than frequent changes of ore mixture, with varying qualities of fuel and flux. It is an advantage to break hard dense ores, especially magnetites.

The approximate saving in lbs. of coke per ton of iron by increase in blast temperature is as follows:—

1,000° to 1,100° F., 50 lbs.
1,100° „ 1,200° „ 40 „
1,200° „ 1,300° „ 30 „

Dry Blast.—Average results with dry blast give a saving of 10 per cent. in fuel consumption with 10 per cent. increase in output, more regular grade of metal, and more regular working conditions.

A blast furnace in its working and results responds readily to improper treatment; proper regulation of flux has much to do with this, and the formation of a correct slag is all important.

The slag should not be too basic or limey; this causes the furnace to become stocky and gob up. If the slag is too acid the furnace will drive harder, but trouble is sure to result with grade and quality of pig.

When the lime content of slag is high it will prove profitable to make such slag into cement; the slag form from furnaces making Bessemer iron will generally be found suitable for this purpose. Most blast-furnace slags can be easily made into first-class building bricks.

The slightest indication of irregular furnace working should be promptly attended to and put right; irregular conditions will probably show first in change of slag or irregular settling of stock. The appearance and degree of fluidity of the slag is the furnaceman's best indication of working conditions.

Irregular working at tuyeres is generally caused by water leakage from jumbos and tuyere blocks. It is quite possible for tuyeres to be shut by water leakage, in spite of very careful watching.

No tuyere in a regular working furnace will close while the blast is on except by water leakage.

Irregular working at tuyeres is sometimes caused by an alteration in burden; in this case every tuyere will give trouble, which will continue till the trouble has been put right.

The best way to open tuyeres that may have been hard closed by slips, irregular working, or water leakage, is by the application of oxygen; the apparatus used is simple and cheap: the worst stuck tuyere can be opened in a few minutes.

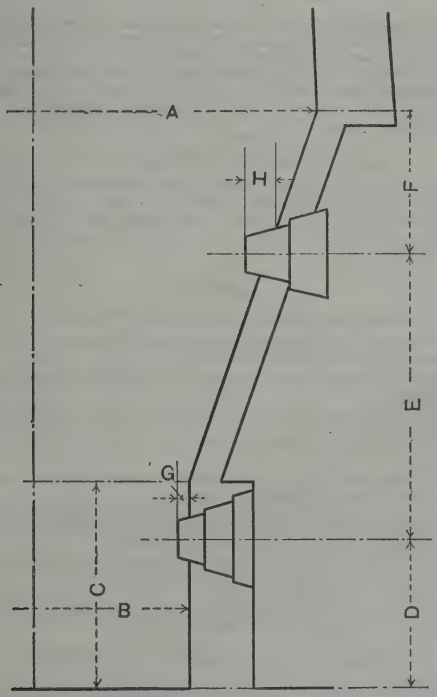

FIG. 20.—Bosh Tuyere.

Bosh tuyeres it is claimed increase the output of a furnace 20 per cent. with a slight increase in fuel consumption and more regular working. Fig. 20 and Table VII. give sizes and position of bosh tuyeres from actual practice.

(*J. S. Hollings.*)

Flue Dust.—The treatment of flue dust has developed into a distinct branch of blast furnace work; the true solution of the problem is to keep the dust in the furnace, thereby increasing production and reducing costs. Flue dust is caused chiefly by (1) fine ores; (2) soft fuel; (3) hard driving; briquetting or sintering gets over the first, but furnace design will need to be adapted to surmount the second and third. Table III., page 2497, gives some striking figures of the production of flue dust per ton of iron in a modern furnace. The recovery of potash from the flue dust and gases has now passed from the theoretical to the practical stage.

'HEENAN' BLAST-FURNACE GAS CLEANSERS.

We are informed by Messrs. Heenan & Froude, Ltd., Worcester, that they have developed a new type of cleanser for dealing with blast-furnace gas. This is capable of dealing with heavy volumes of dust, and is so arranged as to extract a large percentage of the water vapour contained in the hot crude gas.

CUPOLAS.

BLAST-QUANTITY AND PRESSURE IN CUPOLA WORKING.

An average of 120—in terms of quantity of air in pounds, multiplied by $\sqrt{}$ pressure in ounces—is required to melt one ton of ordinary phosphoric iron.

The maximum output of metal melted per hour is more nearly comparative to diameters of cupolas than areas of same.

The maximum output of a cupola will be obtained when the pressure and quantity of the blast in ounces and pounds per minute respectively are so adjusted that $\frac{W\sqrt{P}}{D} = 330$, D being the diameter of the melting zone in feet. Any further increase in the product $W\sqrt{P}$ results in excessive oxidation of the metal in the cupola.

Iron melted in a cupola is affected in hardness directly as the pressure of blast used, so that the total area of the tuyeres employed should be regulated according to the class of iron being melted, small areas being used when greater hardness is required.

The height of the cupola from the top tuyeres to the charging-door sill should *not be less* than two and a half to three times the diameter across the melting zone.

The coke consumption in a well-designed cupola need not be more than 0·075 lb. to 0·09 lb. per pound of ordinary phosphoric iron melted, when the coke contains from 90 to 92 per cent. of carbon. (*F. J. Cook.*)

CENTRIFUGAL FANS FOR CUPOLAS AND SMITH'S FIRES.

To give the high pressure required to supply air to Cupolas and Smith's Fires the fans must be of the 'centrifugal' type and suitably designed. They usually have smaller inlets and outlets than those used for ventilating, as pressure, not volume, is the essential feature.

Care is required in the choice of a suitable fan, as the efficiency varies within wide limits with the design.

The duct to the cupola or fires should be made at least as large as the fan outlet; in long lengths it should be made larger, so as to reduce friction, which increases the power to no purpose. If the ducts are below ground cast iron is the best material; sheet-steel ducts $\frac{1}{8}$ in. thick, with flanged joints, are also very suitable, especially if carried above ground. If earthenware pipes are used great care must be taken to lay them straight, with good, sound, and permanent joints.

Forge Air Pressure.

The air pressure for a forge commonly varies from 2 to 4 ozs. per square inch, with an average of about 3 ozs. A pressure of 4 ozs. at the blower has been recommended when the average number of fires does not exceed ten, and a pressure of 5 ozs. when the number is more than twelve. Small forges with the blower close to them are adequately supplied with 1½ ozs. pressure. If the blower is some distance away and a long discharge pipe with many bends leads to the forge, even though the latter be small, it may be necessary to carry 3 ozs. pressure or more, to overcome the friction in the air ducts. The volume of free air required by the average forge fire is about 140 cubic feet per minute. The exhaust fan for a blacksmith shop should have a capacity approximately four times that of the forge blower, and should operate under a pressure of about ¾ oz.

MUFFLE FURNACES.

Heat Treatment of Metals in Coal-gas Furnaces.

Furnaces of the oven and muffle type heated by several different systems—natural draught, air blast, 'Lopress'—are manufactured for annealing, normalising, case-hardening, tempering, forging, and other heat treatments of iron, steel, and the non-ferrous metals.

Fig. 23 shows an oven furnace heated by the 'Lopress' system, in which gas at ordinary main pressure is used in conjunction with air at approximately 4-in to 6-in. water gauge. No compressor is necessary, the requisite air supply at this pressure being derived from a fan. Very rapid heating and much higher temperatures can be obtained compared with natural-draught heated furnaces. The 'greasy' flame so essential to annealing work on a large scale can be produced to perfection, while economy is ensured by regeneration of the air supply to the burners.

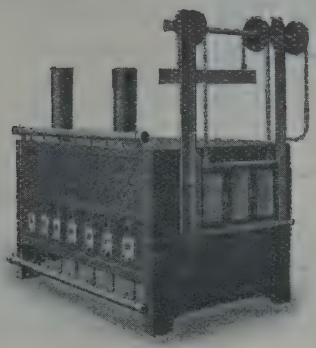

Fig. 23.

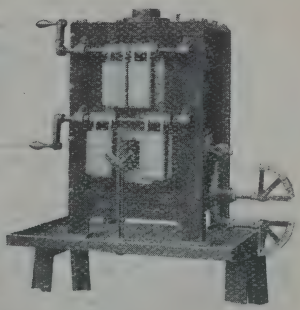

Fig. 24.

The following are figures from actual practice :—

Operation.	Load.	Duration.	Cub. ft. ton.
Annealing H.S. steel	3½ tons	8 hrs.	3,000
,, steel	3½ tons	15½ hrs.	6,000
,, C.I. parts packed in filings in boxes	2,000 lbs.	3 hrs.	3,360

High-speed Tool Steel.*

In no heat treatment of metal is uniformity of furnace temperature more important than in the treatment of high-speed steel. Tool makers nearly always state the exact temperature required for various processes.

* See also p. 1099.

The furnace shown in fig. 24 enables any temperature to be quickly reached and regularly maintained down to the very narrow limits frequently required by particular steels. Whatever the composition of the steel, this furnace enables the operator to produce good tools, giving the maximum of service, and avoiding the waste of expensive material and time due to under, over, or irregular heating, etc.

The upper chamber is heated by waste heat from the lower, and serves to preheat the tools, etc., before they are put into the lower chamber, thus raising them to a medium temperature preparatory to the final rapid heating necessary to bring them to the hardening temperature

CRUCIBLE MELTING FURNACES.

(L. C. Harvey.)

'Lift-out Crucible' or Pit Type Furnaces.—These are supplied where requirements of molten metal are small, or in cases where it is preferable to melt in relatively small capacity crucibles. *Natural Draught Coke Furnaces* can be either connected up to one main flue and chimney or can be provided with smaller collecting flues, each flue having a chimney to serve a small number of fires, or again, each fire can have its own small stack.

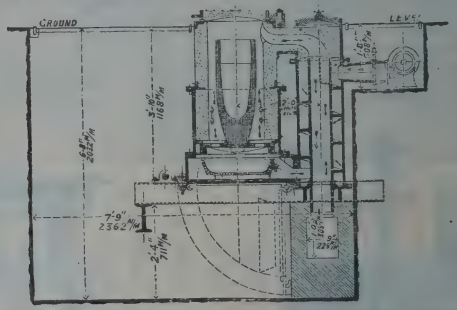

FIG. 25.—Furnace for Coke and Forced Draught. Sectional view, showing ground level.

Forced Draught Coke Furnaces (fig. 25) can be similarly arranged as regards provision for exhausting the waste gases, and as they are not dependent upon chimney pull the heights of stacks are considerably less than those required for natural draught furnaces.

It is usual to supply air from a blower or fan of sufficient capacity to feed any number up to the whole of the plant. Forced draught offers the advantages of (*a*) independence of atmospheric conditions, and, therefore, absence of variation in chimney pull; (*b*) quicker heating qualities of furnaces; (*c*) a greater degree of heat intensity than is possible under all conditions in natural draught furnaces.

Oil-fired Furnaces.—These can be fitted with burners to work with compressed air at 20-30 lbs. per square inch, depending to a large extent upon the temperature desired, the higher pressure effecting a more perfect atomisation of heavy grades of fuel, or with low pressure burners which run with a pressure of only $\frac{3}{4}$ lb. per square inch for all temperatures up to that necessary for melting mild steel and nickel.

The former require an air compressor, which is a relatively expensive machine, and may develop 5 to 10 h.p. per burner, whereas the latter needs only the ordinary open high-speed fan, and the burners will take $1\frac{1}{2}$ to $2\frac{1}{2}$ h.p. according to size of the furnace, etc. Almost any grade of commercial fuel oil can be used with either type of burner, and this is fed to the burners by gravity.

Producer Gas can be applied to lift-out crucible furnaces if these are made in the multiple form, viz. several crucibles in one common melting chamber, or several crucibles in separate chambers, but exhausting into one air or gas heating regenerator.

For ordinary low-power producer gas, 135 to 175 B. Th.U. per cubic foot, is essential to preheat the air or gas supply to about 300° C. for efficient melting of copper alloys; for iron and higher temperature melting, both the gas and air should be supplied at about this temperature.

When using high-power gas, such as water gas of roughly 280 B.Th.U. value per cubic foot, no preheating is required for melting temperature up to about 1,400° C.

Tilting Furnaces *for Coke Fuel* are always of the forced draught pattern, for one of their chief features, quick heating, would be greatly impaired if worked on natural draught. This type of furnace is more efficient than the pit type, and it has the important advantage of melting in greater bulk than can be handled in a lift-out crucible—up to $\frac{1}{2}$ ton of metal at one charge—

and the further advantage of making it possible to mechanically tilt the furnace on a fixed front trunnion, so that the metal can be poured direct into ladles or moulds. In the portable pattern the body portion holding the crucible can be transported by means of an overhead crane to the point at which the molten metal is wanted.

Furnaces for Oil Fuel.—The remarks made above in connection with pit furnaces apply also to the tilting pattern. The economy in oil when melting, say, ½ ton of metal in one crucible with one burner, will be very marked, compared with, say, five burners for five 200-lb. size pit furnaces, and the consequent saving in power for air blowers in equal proportion.

Producer Gas can be applied to tilting furnaces as for pit furnaces, but tilting furnaces being of greater capacity than the latter it becomes possible to run single furnaces with producer gas, the heat in the waste gas being utilised to warm the incoming air or gas supply. For copper alloys it is usual only to preheat the air.

The 'Radiation' Gas-heated Furnaces.
(*Radiation, Ltd.*)

Natural-draught Oven and Muffle Furnaces for Hardening, Case-hardening, Annealing, etc.

These furnaces are of the 'under-fired' type, and are heated by means of gas supplied at normal town's pressure, the burners being so proportioned and located under the furnace hearth as to ensure even heat at the required temperature throughout the whole working chamber. Each burner has separate gas taps and air adjustments. Depending on the class of work, this apparatus can be constructed as either a muffle or oven furnace. The furnaces are frequently constructed with two heating chambers, an arrangement which gives, without lowering temperature in the bottom chamber or increasing the gas consumption, a pre-heating top chamber maintained at a temperature of about 300° C. less than the lower one. Where temperatures of 1,000° C. and over are required, the furnaces are used in conjunction with air-blast burners, as natural-draught furnaces are not recommended above 950° to 1,000° C. The furnaces are also capable of modification to use oil fuel as a heating medium.

Low-pressure Gas and Air Furnaces for Annealing, Case-hardening, Reheating, Hardening, and Forging, etc., etc.

This furnace is 'over-fired,' i.e. the gas supply at normal town's pressure is led through ports at one or both sides, where it comes into contact with the air supplied (at approximately 2 in. w.g.) obtained from a small fan, which air has been previously well pre-heated by being taken through the opposite side of the furnace in fine clay tubes, and then passed along the bottom of furnace in close proximity to waste products. Combustion takes place inside working chamber, the flames produced keep well up and sweep round the arch. The products of combustion then pass to the opposite side of furnace, are carried under the floor and up the other side away to the flue.

Patent Twin-chambered Furnaces for Hardening High-speed Steel.

This twin-chambered furnace is specially designed for the hardening of high-speed steel tools, and combines durability with economy of working. The furnace linings are of exceptional thickness, and the doors are constructed to conserve the heat and protect the operator. The fuel in this case may be either oil or gas, and special attention has been paid in order to secure a reducing atmosphere, in consequence of which the tools can be raised to the necessary high temperature without scaling or blistering. The upper chamber is heated by the waste heat from the lower one, and is used for the preheating of tools before finally raising them to the high temperature required for hardening.

Patent Salt Bath Furnace for Hardening and Heat-treatment of Cast and Special Steels and Reheating of Mild Steel after Carburising.

This furnace is designed for very accurate control, and consists of a metal pot containing fusible salt (pyromelt), which fuses at 670° C. Suspended above this pot is a rising and falling tray, which holds the work and also acts as a stirrer when in the molten liquid. Special provision is made for a pyrometer to be inserted in the liquid, and for protecting it against damage. This apparatus is suitable for heating up to 900° C., but at this high temperature the life of the pots is uncertain. Up to this point, however, heating is under complete control, and any required treatment may be repeated with mechanical precision. The furnace may be heated by coal gas, producer gas, or oil, in conjunction with air under pressure.

Tilting Crucible Furnaces for Melting Copper, Gunmetal, Brass, Aluminium, etc.

This type of furnace is designed for use where a large quantity of metal is to be heated at one time, and where it is important that the heat be maintained while the metal is being poured. The furnace body is constructed in wrought steel, strongly stiffened and lined with fire-brick. It is mounted on trunnions and tilted by means of a hand wheel, operating bevel, and worm gears. These latter are covered in to protect them from damage by sand, etc., and for safety. The furnace is fitted with a loose bottom plate with slag holes, and this can be removed to facilitate the renewal of the base brick. Below the bottom plate is a loose pan, so that should a crucible break, the molten metal runs through the slag holes and is collected, thus preventing damage to burners beneath.

ELECTRIC FURNACES.

(*A. H. Allen, M.I.E.E., and Owen W. Ellis, M.Sc.*)

The classification of electric furnaces has already been dealt with (pp. 2493-2494). It remains to treat in detail of these furnaces and their application industrially.

Electric Furnaces Heated by Resistance Effects.

Those furnaces of this type in which the charge is included in the electric circuit (fig. 26) are of indirect interest only to the engineer. They are employed largely in the manufacture of aluminium, carborundum, calcium carbide, etc.

Those furnaces of this type in which the charge is heated by means of an electrically-heated conductor find extensive employment in laboratories, and are coming into more general use for the annealing and thermal treatment of steel and the melting and heat treatment of non-ferrous alloys.

The smaller furnaces, such as are used in laboratories, are often made after the style of gas-heated muffle furnaces, but in place of gas jets, wire of platinum or incorrodible alloy, heated by the passage of an electric current, is wound round the body of the chamber. Another type consists of a tube of carbon, cut into a spiral or helix, through which the current flows.

Discussing furnaces of the larger type, T. F. Baily states that a 150-kw. annealing furnace heating 1,000 lbs. of steel to 900° C. in one hour consumes 300 kw.-hours per ton. With regard to melting in a shop working 24 hours per day, the following costs were recorded :—

	s.	*d.*
Electricity, 400 kw.-hours per ton at ½*d.*	16	8
Metal loss, 1 per cent. zinc at 5*d.* per lb.	8	4
Labour, 1 man per 600 lbs. per hour at ½*d.* per hour	5	0
Renewals and repairs	4	2
Total per ton of brass melted	£1 14	2

These furnaces are provided with separate heating elements of carbonaceous material, which do not come into contact with the charge, but are made incandescent by the current passing through them, and thus heat the interior of the furnace chamber.

Induction furnaces (figs 27 and 28), which may be classed under this head, find employment in the manufacture of steel. They are able to hold their own against other types of steel-melting furnaces on account of their steady current consumption and low power consumption in the melting of cold stock, but suffer from certain disadvantages of a well-defined character. The heat being generated in the metal and only conducted to the slag renders it impossible to work a fluid basic slag, with the result that desulphurisation of the charge is not so efficiently carried out as in the case of furnaces of the resistance or arc-resistance type. Nor can dephosphorisation be so perfectly attained, since the design of these furnaces militates against ready and complete removal of the oxidising slag needed for the removal of phosphorus. A further disadvantage arises as a result of the continuous circulation of the molten metal in the bath which leads to the erosion of the lining. This, in addition to the corrosive effect of the slag, leads to high figures for lining repairs.

Were the induction furnace of more flexible character and efficient design, it should find wide application in the melting of brass containing as high as 50 per cent. zinc. At present this type of furnace is being experimented with in the direction of non-ferrous alloy melting.

Electric Furnaces heated by Arc Effects.

Only furnaces in which indirect heating of the charge (fig. 29) is carried out are of interest in this connection. The Stassano furnace is the most striking example of this type. The power consumption of arc furnaces is high, and fluctuations in the value of this factor are, when the furnace is being employed in the fusion of cold stock, of high magnitude.

In the melting of copper alloys the indirect arc furnace may be employed economically in large units. For melting brass containing not more than 10 per cent. zinc it has also been used.

Electric Furnaces heated by Combined Resistance and Arc Effects.

By far the largest number of electric furnaces in use industrially are of this type. In this class of furnace an arc is struck between the extremities of vertical electrodes and the liquid or solid furnace charge (fig. 30). In many furnaces of this type negative electrodes are built into the furnace bottom or sides so that current is forced to flow through the bath (fig. 31). In both cases the bath is heated by (i) the heat of the arc and (ii) the heat produced by the resistance of the steel and slag to the passage of electric current.

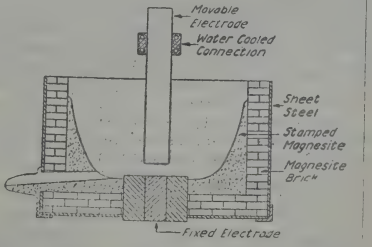

FIG. 31.

Cross Section of Smothered Arc Furnace. Current arcs from the electrode to the charge in which the electrode is plunged and the current passes through the charge to the lower fixed electrode.

The electrodes, which are of graphite or amorphous carbon, are capable of movement in a direction parallel to their axis and are controlled, either by hand or by electrical device, so as to retain the arc at as constant a length as may be desired either for melting, refining, heating, etc., of the metal. In certain cases the practice of completely immersing the electrode in the molten charge—thus utilising the resistance effect of the electric current only—is in vogue.

For making steel the arc resistance type of furnace is that chiefly used, the charge generally consisting of scrap steel. The composition of electric steel can be very accurately controlled, and the proportions of sulphur and phosphorus in the final product can be reduced to mere traces. An improvement in quality is, therefore, to be expected. The most widely used arc-resistance furnace is the Héroult, of which, according to the Society for Electrical Development, 181 were in operation on January 1, 1917, 84 of these being in the United States and Canada. These and similar furnaces are largely used for making small castings in steel, malleable iron, and cast iron, their capacities ranging from 1 to 20 tons ; 6-ton furnaces are very common. Other well-known furnaces of this class are the Girod, Nathusius, Keller, Gronwall, Electro-metals, and Greaves-Etchells. Each of these furnaces is possessed of special characteristics which appeal to individual users. While steel melting and refining, and the production of steel and iron castings, occupy the vast majority of electric furnaces, all the foregoing types can be, and have been, used for melting brass, copper, etc., though it is questionable whether their use for such purposes can be considered as expedient.

Arc-resistance furnaces for steel melting are most frequently lined with basic refractory materials. Acid-lined furnaces are, however, employed, chiefly to melt down high-grade raw materials. The necessity for utilising such materials, for which high prices must be paid, renders the mere melting process a costly one. Further, as the treatment of molten steel on an acid hearth leads to an appreciable gain in those elements, sulphur and phosphorus, most to be avoided, the process is still further limited in its application.

The process employed for the production of steel in basic-lined arc-resistance furnaces is determined by (*i*) the stock on hand and (*ii*) the product desired.

Should the stock on hand be of fair quality, i.e. containing contents of sulphur and phosphorus not above 0·06 per cent., the process may consist of (*i*) the application to the charge of a basic oxidising slag and (*ii*) the conversion of this slag, by means of suitable additions of coal dust and lime, into a reducing slag, which is allowed to remain in contact with the molten steel during the operations of teeming from the furnace and of casting from the ladle. Such additions of ferro-alloys as are required to bring the steel up to the standard required are made when the slag is as completely reducing in character as is possible under the conditions imposed by practice.

If the stock on hand is of poor quality, i.e. should it consist of scrap containing high (from 0·06 to 0·20 per cent.) sulphur and phosphorus, or if it is desired to specially refine stock of fair quality, the first slag—the basic oxidising slag—is removed from the surface of the steel in the furnace. The removal of this slag implies the removal of the major portion of the phosphorus from the steel, and unless the removal be very complete a return of phosphorus to the steel may be expected, the content of phosphorus returning to the steel under these conditions being roughly proportional to the amount of slag allowed to remain upon the charge. Occasionally it may be necessary to apply a further oxidising slag to the metal in the bath ; generally, however, one slag only is made. The first slag having been removed, deoxidation and desulphurisation are effected by the medium of a slag composed largely of calcium silicate. The 'physic' required to provide for carbon, manganese, etc., in the finished steel may be added immediately after the first slag has been removed. Generally speaking, the additions are made at a later stage in the process. The complete deoxidation of the metal is made evident by the appearance of the slag, which, the above conditions prevailing, decrepitates spontaneously and is practically white when cool.

Melting and refining carried out on a basic hearth results in a practically complete loss of carbon, silicon and manganese, and a very appreciable loss of sulphur, phosphorus and such elements as chromium, molybdenum, etc.

The possible uses of the electric furnace in the steel foundry have been tabulated by J. H. Hall :—

Melt scrap	Impure : eliminate phosphorus and sulphur. Pure : get hot and cast. Alloy steels.
Melt pig and more or less scrap. Eliminate C, Si, Mn.	Impure : eliminate phosphorus and sulphur. Pure : get hot and cast.
Treat hot metal	From cupola : eliminate C, Si, Mn, S and P. From acid Bessemer or open hearth : eliminate S and P. From basic open hearth : eliminate S and P.
Melt pig and scrap and treat cupola metal	Eliminate C, P and S without loss of Mn and Si. (Greene's process.)

The arc-resistance furnace proved to be of value during the war in the preparation of high-grade pig iron to replace the Swedish pig iron so much sought after for the preparation of high-grade steels.

According to E. K. Scott, a 10-cwt. steel-melting furnace running 9 charges a day will do as much as 36 crucible-steel furnace holes, each accommodating two 56-lb. pots, and can be operated by one man and an ammeter boy, whereas the crucible furnaces require 15 men, most of them skilled. The electric furnace, with its transformer and switch-gear, occupies one quarter as much space as the crucible plant, and costs half as much to instal. It can deal with a charge consisting entirely of turnings, millings, etc., whilst in the crucible-steel process only a very limited quantity of turnings can be used. The renewal of the furnace linings costs less than that of crucibles for the same output. Consequently the electric-steel furnace has been largely adopted in Sheffield in place of crucible furnaces.

The chief **losses** in electric furnaces are due to radiation from the walls and conduction through the electrodes. Since the radiation losses increase as the square and the capacity as the cube of the linear dimensions of furnaces, it is obvious that large installations are more economical than small ones. Conduction losses can be reduced to a minimum by suitably designing the electrodes.

Although, with coal at 14*s.* per ton and electrical energy at ½*d.* per kw.-hour, the latter costs twenty-eight times as much as the former per British thermal unit purchased, the efficiency with which the electrical energy is applied is so much higher that the difference is largely neutralised, and in the case of crucible steel is completely wiped out. In addition, the labour cost is greatly reduced with electric furnaces and there is a considerable economy of space and buildings, while the steel produced is of higher quality and uniformity than by any other method.

A useful method of calculating heat flow through the furnace walls, etc., has been developed by Carl Hering on the lines of Ohm's law. If—

W = heat flow in watts,

T = drop in temperature in degrees C.,

R = thermal resistance in 'thermal ohms,'

then—

$$W = T/R.$$

A thermal ohm is that thermal resistance which requires a drop of temperature of 1° C. to produce one watt of heat flow and = 4·2 gramme-calorie units; 1 gramme-calorie unit of thermal resistance = 0·24 thermal ohm.

Assuming that the electrodes are of uniform section, and that no lateral loss of heat takes place—conditions which are only approximately fulfilled in practice—Hering finds that the total loss of heat through the cold end of the electrode equals the sum of the loss by heat conduction alone (i.e. when no current is flowing) and half the T^2R loss. This combined loss is least when the loss by heat conduction alone equals half the T^2R loss; the total loss then equals the T^2R loss, and no heat will be conducted out of the furnace by the electrodes. This minimum loss is dependent only on the material of the electrodes, the current, and the temperature, but not on the absolute dimensions; it fixes the ratio of cross-section of electrode to length. In the case of a furnace working at 1,400° C., the cool end of the electrode being at 100° C., the length of the electrode 20 ins., and the current 10,000 amperes, the following dimensions were given by Hering's method of calculation:—

Carbon, 12·5 ins. diameter, loss of power in electrode 23·4 kw.

Graphite, 7·1 ins. diameter, loss of power 15·1 kw.

Iron, 4·8 ins. diameter, loss of power 4·6 kw. (*Stansfield.*)

F. T. Snyder states that in the case of a furnace melting 1,000 tons of steel a month, the cost of renewing the electrodes, plus the cost of the heat conducted out of the furnace by them, represents an expenditure of some 1,200*l.* a year per electrode. Hence the type of furnace having the fewest electrodes has an advantage in this respect. By using the metal bath as one terminal of the arc, a furnace can be operated with one carbon electrode per arc. The furnace lining becomes conducting at very high temperatures, and this fact limits the voltage between two electrodes passing through the same roof to a maximum of 110 volts to avoid serious leakage of current. The bulk of the cost of renewing refractory linings is due to roof wear round the

electrodes, and for the size of furnace above mentioned can be kept down to 800*l.* per annum per electrode. The higher the power input the quicker is the heating and the greater the efficiency of the furnace. With three electrodes the limit of power is soon reached, owing to lack of room to space the electrodes sufficiently far apart to prevent current leakage through the roof lining, but with a single electrode there is no such limit to the power input.

The power, etc., provided in connection with Héroult furnaces used by the United States Steel Corporation are given in the following table, which applies to cold charges; if the charge is put into the furnace in a molten condition about half this power suffices :—

POWER REQUIRED FOR ELECTRIC FURNACES.

Size of Furnace, tons.	Transformer capacity, kva.	Amperes, per phase.	Square inches Copper, per phase.
1	375	2,250	3
2	600	3,600	5
3	750	4,500	6
4	900	5,400	7
6	1,200	7,200	9
10	2,000	12,000	16
15	3,000	18,000	24

The voltage used in arc furnaces depends upon the current and the length of the arc. In three-phase furnaces it ranges between 75 and 100 volts, and in single-phase furnaces between 150 and 200 volts. In resistance furnaces the voltage at starting, with a cold charge, may be 400 volts, decreasing as the charge heats up to 35–60 volts. The consumption of the electrodes varies widely according to the conditions obtaining, from 3½ to 20 lbs. per ton of steel produced. The furnace bottoms last from 1 to 3 years, the walls from 100 to 300 heats, and the roof from 50 to 200 heats. To make ordinary carbon steel of crucible quality with a 6-ton furnace requires from 550 to 750 kw.-hours per ton, starting cold. In smaller furnaces the input per ton is greater. The following figures for a Rennerfelt furnace are due to C. H. Vom Baur.

ENERGY REQUIRED IN TREATING VARIOUS METALS.

	Kw.-hours per ton.
Melting red brass	168
„ pure copper	197
„ white iron	290
„ gray iron	325
„ 80 per cent. ferro-manganese	441
„ and refining steel scrap on a basic bottom	700

The power factor of the arc resistance furnace varies from 85 per cent. to more than 90 per cent.; that of the resistance type from 90 to 97 per cent.; that of the induction furnace varies from 50 to 60 per cent. only.

The efficiency of a Héroult furnace was tested with a charge consisting of 5,733 lbs. steel scrap, 430 lbs. iron ore, 346 lbs. lime. The input was 215 kws. for the first hour, at 110 volts, and afterwards 342 kws. The total time taken to melt the charge was 5⅓ hours, and the total energy input for melting was 1,680 kw.-hours. The ratio of heat utilised to heat supplied (the efficiency) was 76·5 per cent. The time required for the purification and carburisation of the steel was 3 hours, and the result was 5,161 lbs. of tool steel. The total consumption of energy was 2,580 kw.-hours, or 0·171 e.h.p.-year per ton of steel.

The leads from transformers to electric furnaces should be as short and direct as possible, and close together, as the voltage drop due to their self-inductance and the very large currents is considerable, resulting in a low power factor. The conductors should be wide thin bars, or tubes, to prevent loss of energy due to the tendency of alternating current to flow in the skin of the conductor.

ELECTRICAL RESISTIVITY OF MATERIALS, OHMS PER INCH CUBE.

Material.	Cold.	Hot.	Temperature ° C.
Graphite	0·00034	0·00031	100–2000
Carbon	0·0018	0·0014	100–2000
Silicate slag	∞	1 to 2	Molten
Fire bricks (various)	∞	8 to 24	850
		24 to 300	815

(*Stansfield.*)

FURNACE CONSTRUCTION.

The following are points requiring special attention in the construction of furnaces :—

1. Sections of furnaces such as are exposed to differing physical and chemical actions should be united in such a manner as to allow of free and independent movement and as to be subject to independent condition.

2. Such sections as are exposed to high temperatures should be made thin and should, when possible, be water-cooled; such sections as are exposed to low temperatures should be made of such a thickness as will reduce thermal losses due to radiation and conduction to a minimum.

3. The interiors of furnaces should be constructed so as to resist mechanical, physical and chemical wear. With this end in view choice must be made of suitable materials of construction and of efficient design. In this connection note should be made of the following factors :—

(*a*) The action of heat.
(*b*) The erosive and corrosive actions of flame, slag, etc.
(*c*) The mechanical wear due to abrasion by the solid charge, etc.

4. The exteriors of furnaces should be supported and strengthened in such a way as to allow of the free expansion and contraction of the body. The foundations of all furnaces must be of a strong and rigid character.

MELTING POINTS OF REFRACTORY MATERIALS.

	° C.
Alumina (pure)	2010†
Bauxite	1820†
Bauxite brick	1565 to 1785†
Bauxite clay	1795†
Chromite	2180†
Chromite brick	2050†
Fireclay brick—Highest grade	1843*
General grade	1650 (average)*
Ditto	1649 (average of 41 samples)†
Ganister	1700 to 1800
Kaolin	1735 to 1740†
Magnesia brick	2165
Silica—Pure	1750†
Pure	1830*
Pure, with 14·5 per cent. alumina	1690*
Pure, with 63·0 per cent. alumina	1890*
Brick	1700 to 1750†

The melting points have been considered to be those temperatures at which the material in question was first seen to flow easily.

* Boudouard.
† Kanolt—'Iron and Coal Trades Review,' vol. lxxxv. p. 309.

FURNACE EFFICIENCY.

The thermal efficiency of furnaces may be stated either absolutely or relatively :—

$$\text{Absolute furnace efficiency} = \frac{\text{Net thermal effect produced}}{\text{Calorific power of the fuel}}.$$

$$\text{Relative thermal efficiency} = \frac{\text{Net thermal effect produced}}{\text{Actual calories realised}}.$$

Owing to the large variation in the actual number of calories realised in individual furnaces it is general to employ the former of the above ratios. In order that a determination of the absolute efficiency of a given furnace may be made, a knowledge of the heat-absorbing and the heat-producing factors that are likely to be encountered in practice, of which a number are tabulated below, is required.

(*A*) Heat-absorbing Factors.

1. Heat absorbed by fume, gases, etc.
2. Heat removed by such solids and liquids as are periodically or continuously removed from the furnace.
3. Heat lost by radiation and conduction.
4. Heat absorbed owing to endothermic reactions within the furnace.

(*B*) Heat-producing Factors.

1. Heat supplied to the furnace by the combustion of fuel either inside or outside the furnace.
2. Heat added by such solids and liquids as are periodically or continuously charged into the furnace.
3. Heat gained owing to exothermic reactions within the furnace.

The thermal efficiency of the furnace is represented by the ratio of the heat-absorbing factors to the heat-producing factors.

Latent Heat of Fusion of Metals.

The latent heat of fusion is the number of gram calories required to convert one gram of substance from solid into liquid without change of temperature :—

Mercury	2·8 calories.	Platinum	27·1 calories.
Lead*	5·5 ,,	Sodium	31·7 ,,
Bismuth*	10·2 ,,	Palladium	36·3 ,,
Cadmium*	10·8 ,,	Manganese*	36·7 ,,
Tin*	13·8 ,,	Antimony*	38·9 ,,
Potassium	15·7 ,,	Copper	41·0 ,,
Gold*	15·9 ,,	Nickel*	56·1 ,,
Iron	(See note).	Cobalt*	58·2 ,,
Silver*	26·0 calories.	Aluminium*	94·0 ,,
Zinc*	23·0 ,,		

* Values after Wüst. 'Stahl und Eisen,' 1918, 38, 177.

NOTE.—The latent heat of fusion of iron as determined by Campbell (and confirmed by Desch) from freezing-point depression data is 20·1. C. Brisker (1908), as a result of an examination of Carpenter and Keeling's freezing-point determinations of the iron-carbon system, has arrived at the value 31·6 for this element. Crumer gives values of 23 and 33 for gray and white cast iron respectively. Wüst obtained the value 49·4 for this factor.

Heat and Electrical Energy required for Fusion of Metals.

The following table (after Stansfield) gives the heat and electrical energy required to melt various metals, per lb. :—

	Calb.†	Watt-hours.		Calb.†	Watt-hours.
Tin	28	15	Copper	162	85
Lead	16	8	Cast iron (gray)	245	129
Zinc	68	36	Tool steel (1 % C.)	300	158
Aluminium	258	136	Wrought iron	343	181
Brass	130	69			

(See also p. 2518.)

† *Calb.*—The amount of heat required to raise one pound of water through one degree Centigrade.

Calorie.—The amount of heat required to raise one gram of water through one degree Centigrade.

TEMPERATURE CONTROL OF FURNACES—PYROMETRY.

Determination of Calorific Intensity.

The calorific intensity of a substance is the theoretical maximum temperature attained during the perfect combustion of the same in air at 0° C. and 760 mm. pressure, and is inversely proportional to the time occupied in attaining to this temperature. The calorific intensity of a substance may be determined by calculation or by experiment.

Calculation.

Let C = the calorific power of the substance,
T = the rise in temperature during combustion,
$w, w', w'', —$ = the weights of the products of combustion,
$s, s', s'', —$ = the specific heats of the products of combustion,

then

$$T = \frac{C}{ws + w's' + w''s'' + \text{etc. etc.}}$$

for the fuel at 0° C. and 760 mm. pressure.

The calorific intensity of a fuel (by formula) will be seen to be directly proportional to the calorific power of the fuel and inversely proportional to the weights and the specific heats of the products of combustion.

The calorific power can be raised by

(*a*) Superheating the fuel.
(*b*) Superheating the air needed for the combustion of the fuel.
(*c*) Using a minimum of excess air.
(*d*) Increasing the proportion of oxygen in the air.
(*e*) Reducing the proportion of incombustible material in the fuel.

Experiment.

The calorific intensity of a fuel may be determined by experiment. For the purpose in question a variety of instruments has been designed, almost every thermal property of matter having been employed as a basis for the construction and calibration of these instruments, which are generally known as pyrometers.

Reference may be made to the Bulletin of the United States Geographical Survey, No. 54 (1889), where the following classification of the properties on which the construction of pyrometers has been founded is given :—

1. Dilatation of solids:
   (*a*) A single solid.
   (*b*) Two solids acting differentially.
2. Dilatation of liquids.
3. Dilatation of gases :
   (*a*) Expansion measured in volume, manometrically.
   (*b*) Expansion measured in pressure, manometrically.
   (*c*) Expansion measured in volume, by displacement.
4. Vapour tension.
5. Dissociation.
6. Fusion.
7. Ebullition.
8. Specific heat.
9. Heat conduction.
10. Heat radiation.
11. Viscosity :
    (*a*) Of solids.
    (*b*) Of liquids.
    (*c*) Of gases.
12. Spectrophotometry and colour. Rotary polarisation.
13. Acoustics (wave length).
14. Thermo-electrics.
15. Magnetic moment.
16. Miscellaneous.

Expansion Type Thermometers.

The mercurial thermometer is most important for use at about atmospheric temperatures, largely on account of the wide range of temperatures through which mercury is liquid, —39° C. to 357° C. If a high-grade mercurial thermometer has been calibrated at the National

Physical Laboratory, it is possible to measure temperatures throughout its range to an accuracy of 0·001° C. By the use of inert gases (nitrogen or carbon dioxide) under pressure in the tube of a thermometer, the boiling point of the mercury may be raised to allow temperatures up to 540° C. to be determined, at which temperature the glass softens. Quartz thermometers containing mercury under pressure can be used up to 700° C. By using tin instead of mercury the maximum limit may be raised to 1000° C. Steel tube mercurial thermometers, in which the capillary is attached to a form of a Bourdon pressure gauge, are not easily broken, and may be relied upon up to 540° C.

Fusion Pyrometers.

Observations of the fusion of metals, alloys, salts or mixtures of salts enable the observer to judge the temperature reached in a furnace at the moment of fusion, given that the temperature of fusion of the material employed is known prior to its introduction into the furnace. Fusion pyrometers are most suitable for the registration of maximum temperatures, after the attainment of which the source of heat may be eliminated and the furnace or heated object allowed to cool.

METALS.

The base metals have the disadvantage of ready oxidation; the precious metals offer only a limited number of definite temperatures.

ALLOYS.

Only eutectic alloys (see p. 2527) and solid solutions (see p. 2527) are of value. Base metal alloys being subject to oxidation, only precious metal alloys remain as suitable fusion pyrometers. Both the alloys of silver and gold and those of gold and platinum have been employed for pyrometric work, the latter, according to Séger, being satisfactory up to a temperature of 1200° C. only.

SALTS.

The following are the melting points of a number of metallic salts that have found use in pyrometric work :—

SALT.	MELTING POINT.	
Calcium nitrate	561° C.	1042° F.
Strontium nitrate	570 ,,	1058 ,,
Barium nitrate	593 ,,	1099 ,,
Potassium iodide	705 ,,	1301 ,,
Potassium bromide	750 ,,	1382 ,,
Potassium chloride	790 ,,	1454 ,,
Sodium chloride	800 ,,	1472 ,,
Sodium carbonate	849 ,,	1560 ,,
Sodium sulphate	880 ,,	1616 ,,
Barium chloride	960 ,,	1760 ,,
Potassium sulphate	1050 ,,	1922 ,,

MIXTURES OF SALTS.

Under this heading may be included two important types of fusion pyrometers :—

(*a*) Séger cones.
(*b*) Sentinel pyrometers.

SÉGER CONES.

These are small three-sided pyramids, each about 2½ ins. high and about ½ in. wide at the base. The term 'cone' is rather misleading, as they are more pyramidal than conical. They are made of a finely ground mixture of felspar, china clay, and flint, the composition of the mixture depending on the temperature to be indicated. For the lower members of the series other mixtures are used.

These cones were invented by the late Dr. Séger of Berlin, in order to provide some means of recording the effect of heat on various porcelains. Their shape and composition are such that when heated to their indicating temperature at a reasonably slow rate and under suitable conditions they bend over slowly from the upright position possessed by them when placed in the kiln or oven and gradually form an arch. When the top has almost reached the same level as the base the indicating temperature is reached. A further rise in temperature will cause the cone to collapse and form a shapeless, glazed mass.

It is customary to employ three different cones at a time; the first will indicate a temperature about 20 degrees Cent. below the one required to be known, the second cone will indicate the desired temperature (such as the finishing temperature of a glaze) and the third cone will serve as an indicator that the required temperature has not been exceeded by 20 degrees. The composition of the cones is such that the difference in temperature shown between two successive cones is about 20 degrees, though they are not quite regular in this respect.

It is important to remember that Séger cones do not serve as strict indicators of temperature in the sense that a thermometer does. If heated too rapidly a much higher temperature may be reached than is normally required to bend a cone, and which they are supposed to indicate. Under ordinary conditions of use, however, it is easy to find which cones correspond to the temperatures or conditions of heating which it is required to control, and Séger cones are, therefore, invaluable when they are rightly used. They serve as excellent indicators of the effect of heat on pottery and similar materials, and as it is this, rather than the mere momentary temperature which is important, they have advantages not possessed by a pyrometer or high temperature thermometer.

They were originally made only at Dr. Séger's laboratory in Berlin, but since 1914 they have also been made at the Pottery School, Stoke-on-Trent, and sold by Messrs. Keeling & Walker, Sutherland Mills, Stoke-on-Trent.

Owing to their cheapness and the difficulty of ensuring their accuracy when made by amateurs it is usually better to purchase the cones rather than to attempt to make them.

The following temperatures are those nominally associated with Seger cones, but, as explained above, it is preferable to refer to the number of the cone rather than to the temperature.

SÉGER CONES AND TEMPERATURES.

Séger Cone.	Deg. Cent.	Deg. Fah.	Séger Cone.	Deg. Cent.	Deg. Fah.	Séger Cone.	Deg. Cent.	Deg. Fah.	Séger Cone.	Deg. Cent.	Deg. Fah.

Silica . . 52·50 per cent.	Magnesia . . 0·54 per cent.	Potash and soda . traces
Alumina . 45·22 „	Lime . . . 0·50 „	Loss on ignition . 0·78 per cent.
Iron oxide . 0·81 „		

Sentinel Pyrometers.

These are small cylinders, measuring about ¾ in. by ½ in. and manufactured from salt mixtures of definite melting points. Only such mixtures can be utilised as are formed of salts that neither dissociate nor corrode when in the molten state. Brearley states that 'mixtures of salts, after being melted together and ground to a very fine powder, may be made into an adhesive paste with vaseline, and applied to many purposes for which no ordinary pyrometer is available. In the smith's hearth, for example, a tool may be heated to low redness and smeared near the point with a small portion of a paste whose melting point is, say, 770° C. The tool is then reheated directly in the fire or protected from the coke by a piece of scrap, wrought or cast iron piping, until the white mark left by the thin layer of the salt mixture disappears. This indicates that the steel itself has nearly reached the desired temperature and may be quenched.'

The following are the melting points of a number of mixtures of salts:—

Salt.	Parts by Weight.	Salt.	Parts by Weight.	Deg.
Potassium carbonate .	50	Potassium chloride	50	580 C.
Sodium chloride . .	30	Ditto	70	625 C.
Ditto	42	Ditto	58	655 C.
Potassium sulphate .	20	Sodium sulphate	80	825C.
Ditto	30	Ditto	70	830 C.
Ditto	50	Ditto	50	850 C.

Heat Radiation Pyrometers.

In this type of instrument the relation between the effect of radiant heat on suitably chosen thermal elements and the temperature of the radiating body is observed. The Féry Radiation Pyrometer (Cambridge and Paul Instrument Co.) is an example of this class of instrument.

In this pyrometer the rays from the hot body are received on a concave mirror, which can so be adjusted that the rays form a heat image which covers a small sensitive element permanently fixed on a line through the axis of the mirror. The sensitive element consists of a delicately adjusted thermo-couple, which delivers current to a millivoltmeter, calibrated, if desired, to read the temperature of the body, whence the heat rays are emanating, directly. In both cases suitable means are provided for ensuring that the sensitive element is completely covered by the image of the radiant body.

In order that correct results may be obtained when using pyrometers of the radiation type it is necessary that the hot body sighted should be enclosed within a vessel whose walls are approximately at the same temperature as the body itself. If this precaution is not observed the reading obtained will be lower than the true temperature of the body, the degree of inaccuracy being dependent almost entirely on the nature of the surface of the body in question.

Optical Pyrometers.

Approximate estimations of the temperatures of incandescent bodies may be made by visual observation. Numerous colour scales have been proposed, but those due to Howe and Taylor and White are generally accepted as the most accurate. The following table (based on one by Howe) is of value in this connection.

Taylor and White.		Howe.	
Name of colour.	Degrees C.	Name of colour	Degrees C.
—	—	Lowest visible red in the dark	470
—	—	Lowest visible red in daylight	475
Dull red, blood red, low red	566	Dull red	550–625
Dark cherry red	635	—	—
Cherry, full red	746	Full cherry	700
Light red, bright cherry, light cherry	843	Light red	850
Orange	899	—	—
Light orange	941	—	—
Yellow	996	Full yellow	950-1000
Light yellow	1079	Light yellow	1050
White	1205	White	1150

The design of optical pyrometers is dependent on the fact that the intensity of the light rays emitted from an incandescent 'black body' is directly proportional to the temperature of the 'body.'

The Mésuré and Nouel Pyrometric Telescope consists of two suitably mounted Nicol prisms, so adjusted that their planes are at right angles to one another when the scale of the instrument is at zero and between which is placed a quartz plate cut perpendicularly to its axis. When the incandescent body is observed through the instrument it is necessary to rotate one of the Nicols in order to extinguish the emitted light. The angle of rotation is proportional to the thickness of the quartz plate, which is a constant for any given instrument, and inversely proportional to the square root of the wave length of the observed light. The wave length of the observed light being proportional to the intensity of the light, the angle of rotation of the analyser or polariser is a measure of the temperature of the incandescent body.

The Cornu-Le Chatelier Photometric Pyrometer is designed to measure the intensity of the light emitted by an incandescent body by reducing this intensity until it corresponds to that of the light emitted by a standard lamp. The reduction required is inversely proportional to the temperature of the hot body.

The Wanner Photometric Pyrometer likewise compares the intensities of the lights emitted by the incandescent body and a standard body respectively. In this instrument, however, spectra of the two sources of light are, firstly, broken up into two polarised planes at right angles to one another; secondly, adjusted so that only the narrow red bands of each spectrum are transmitted

further; and, thirdly, so brought into vision that the intensity of either field, both being in visual contact, can be strengthened or weakened, until they are equally intense, by rotation of a Nicol prism. The amount of rotation, which can be observed on a suitably situated scale, serves to measure the intensity of the emitted light, and hence to define the required temperature.

The Cambridge Optical Pyrometer is, in principle, the same as the foregoing, and is invaluable for temperature measurements between 700° and 4000° C.

Thermo-Electric Pyrometers.

This type of pyrometer is dependent for its action upon the fact that a current is produced within a closed circuit formed of two dissimilar metals when the junction between the two metals is heated, the current being proportional to the absolute temperature of the junction.

The essential features of this pyrometer are two thin insulated rods or wires of dissimilar metals coupled at one of their ends and connected at their other ends to separate leads. The connection between the two metals and the leads, which is known as the 'cold-junction,' is enclosed within suitably designed apparatus that can be retained at a known constant temperature. The leads from the 'cold-junction' pass to some form of electrical instrument capable of registering or recording changes in the P. D. produced in the now closed circuit when the thermo-couple is heated or cooled.

The number of metals and alloys available for the manufacture of thermo-couples are few. The following are among those most generally employed :—

Couple.	Range.
Platinum—platinum rhodium	Up to 1400° C.
Platinum—platinum iridium	„ 1000 „
Nickel—nickel chromium	„ 800 „
Silver constantan	„ 600 „
Copper constantan	„ 500 „
Iron constantan	„ 500 „

For the estimation of temperatures above the melting-point of platinum the iridium-iridium-ruthenium couple has been suggested, but it is considered unlikely that the same would prove efficient, on account of the known volatility of iridium at such temperatures.

Union between couple *wires* is effected by fusion in the electric arc or oxyhydrogen flame in the case of couples having a platinum base, by soldering or brazing in the case of base-metal couples or by twisting. Union between the wires and the leads can be effected as above or by means of electrical clamps.

The couple wires, when in use, are generally protected by tubes of nichrome, fireclay, silica or glazed porcelain, the last being particularly useful when it is desired to defend the wires against the deleterious action of hot gases. When necessary, protection is afforded these tubes by enclosing them in steel jackets.

Heavier types of thermo-electric pyrometers consist of a *rod* of one metal fitted tightly into one end of a cylinder concentric with the rod and of another metal and insulated from the same by suitable means.

Calibration of thermo-electric pyrometers is effected by immersing the protected couple in substances or the vapour of substances whose melting or boiling points are known. The couple, being subject to like thermal changes as the substance, causes a fluctuation in the current flowing within the closed circuit, which fluctuation is registered by the instrument within the circuit. For example, while solidification of a metal in which the protected couple is immersed is in progress a constant reading is obtained on the instrument. This value is observed, and is recorded on a graph against the melting point of the metal as ordinate. A series of such points may be obtained by employing a number of metals in similar manner to that already described, and, these points being united, a curve is obtained from which the temperature corresponding to any given reading of the instrument may be abstracted.

The following are the melting points on the thermo-dynamic scale used by the Washington Bureau of Standards as standard temperatures in the standardisation of thermometers and pyrometers :—

Mercury	— 38·9° C.	Antimony	630·0° C.	Nickel	1452° C.
Tin	231·9 „	Aluminium	658·7 „	Iron	1520 „
Cadmium	320·9 „	Silver	960·5 „	Palladium	1549 „
Lead	327·4 „	Gold	1063·0 „	Platinum	1755 „
Zinc	419·4 „	Copper	1083·0 „	Tungsten	3000 „

At temperatures of 1000° C. the error is of the order of 0·1° C., at the melting point of platinum 5° C., at that of tungsten 100° C. A further table of other standard temperatures is given in which the following are included :—Normal boiling-point of oxygen 180·0°, sublimation of carbon

dioxide in an inert liquid 78·5°, normal boiling point of water 100°, of naphthalene 217·96°, of benzophenone 305·9°, of sulphur 444·6°, freezing point of sodium chloride 801° C.

In the *Physical Review* the melting point of rhodium is estimated to be at 1907 or 1968° C. and that of iridium as 2292 or 2388° C. That of silicon is placed at 1434 or 1452° C. and that of palladium at 1548 or 1576° C. The reason for the two figures is due to the fact that the calculations are based on different estimates of the melting-point of platinum, which has been placed at 1745° C. by some experimenters and at 1789° C. by others.

Electric Resistance Pyrometers.

In these instruments advantage is taken of the change of resistance of a wire with temperature. Platinum wire is generally employed. The essential features of the commercial apparatus are a coil of fine platinum wire, enclosed in a suitably designed protecting tube, a cell or accumulator for the supply of current to the wire and an indicator or recorder on which the temperature may be read off directly.

In the original type of this instrument errors due to the residual strain and impurities in the lead wires entered, but later instruments are designed with 'compensating wires,' whose component parts are equal in resistance to and are so arranged that they are heated to the same temperature as corresponding parts of the lead wires. Changes in resistance in the lead wires are compensated by equal changes in the 'compensating wires.'

The resistance pyrometer (after Callendar) is represented diagrammatically in fig. 32.

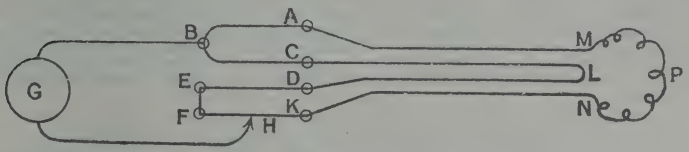

FIG. 32.

P represents the pyrometer coil; AM, KN the lead wires; CL, DL the 'compensating wires'; FK a bridge wire with scale, so arranged that 1 cm. length of the same corresponds to 1° C. rise or fall of the temperature, H the sliding contact piece, and G a galvanometer. AB and BC are wires of equal resistance. DE represents a set of resistance coils. In practice AB, BC and DE can be replaced by a post office box. Balance is obtained by the adjustment of the resistances in DE and the sliding of the contact piece H. The resistance of the pyrometer coil is given by the sum of the coils DE and the bridge wire scale reading.

Resistance pyrometers are accurate from 0° C. to 1000° C., and are employed industrially wherever reliable measurement is essential. They suffer owing to their high first cost and their fragile character. There are, however, large numbers of this type of pyrometer in use commercially.

METALS AND ALLOYS.

ALLOYS.

There are three well-recognised types of alloys:—

(i) Conglomerates of metals, or of metals and non-metals.
(ii) Homogeneous mixtures of metals, or of metals and non-metals.
(iii) Inter-metallic compounds, or compounds of metals with non-metals.

(i.)

In this type of alloy the component elements or their compounds crystallise out from the molten alloy in a practically pure state, and the addition of one component to the other results —within certain limits—in a lowering of the solidifying point of the resulting alloy. The alloy having the lowest solidifying point in such a series is called the 'eutectic.' Lead-tin alloys are of this type.

(ii.)

In this type of alloy the component metals do not crystallise out from the molten alloy in the pure state, but contain on freezing more or less of each other in solid solution. Copper-nickel alloys are of this type.

(iii.)

Inter-metallic compounds behave similarly to pure metals, crystallising in like manner. Copper and zinc form a compound Cu_2Zn_3, which is extremely hard and brittle.

IRON.

IRON (FERRITE).

Chemically pure iron is not an article of commerce at the present time. Iron has been obtained by electrolytic deposition of a degree of purity greater than 99·9 per cent. iron, while the American Rolling Mills Co. manufacture a commercial product which they claim to contain 99·84 per cent. of iron.

Stead, by extrapolation, has arrived at the following figures for the approximate mechanical properties of pure unworked iron :—

Yield point	9 tons per square inch.	Elongation	51 per cent. (length/area = 8).
Maximum stress	17 ditto.	Reduction in area	84 per cent.

The term ' ferrite ' is applied to pure iron when it is considered as a microscopical constituent of iron or steel. Pure iron is composed of polyhedral crystallites of ferrite.

Carbon, manganese, silicon, sulphur, phosphorus, arsenic, molybdenum, etc., all have effect on the iron in which they occur and are frequently added with a view to obtain alloys having more or less definite physical and mechanical properties.

INGOT IRON.

' Ingot Iron ' is the generic name of a commercially pure iron produced under patents owned by the International Metal Products Company. The manufacture of the metal in Great Britain is controlled by The Armco International Corporation, which company also undertakes the sale of the metal in various forms throughout the world, through suitable agents and representatives.

Ingot Iron, unlike Puddled Wrought Iron, is produced in the basic open hearth furnace, and in view of a certain amount of difficulty in finding an acceptable definition of ' iron ' and in differentiating between ' iron ' and ' steel,' it is well to quote the definitions advanced by Dr. Albert Sauveur, who received last year's Bessemer Medal given by the British Iron and Steel Institute. Dr. Sauveur says :—

' COMMERCIAL IRON is the element iron as pure as it can be commercially produced.

' INGOT IRON is commercial iron which has been produced in a fluid condition and cast.

' WROUGHT IRON is a ferrous metal which is malleable and which has been produced from a pasty condition.

' STEEL is an alloy of iron and carbon which is malleable, usually containing substantial quantities of manganese.'

' ARMCO ' INGOT IRON is the purest iron which can be produced in commercial quantities, and owes its origin to a Governmental Committee of Inquiry appointed to consider the premature and uneven corrosion of steel fence wire. The findings of this Committee led to the conclusion that pitting in steel is caused by electrolytic action set up between the impurities it contains and the pure metal as opposing poles, and whatever form of moisture intervenes. After studying this report the producers of Ingot Iron, then a small concern, set themselves the task of producing a ferrous metal free, or nearly free, from those metalloids, impurities, and gases which occur in steel, and they succeeded in evolving a process for manufacturing commercially pure iron, which is utilised throughout the world.

' Armco ' Ingot Iron possesses many special characteristics, some or all of which will appeal to fabricators and users in many industries. The principal points of merit are as follows :—

Chemical Purity.—' Armco ' Ingot Iron contains less than one-sixth of 1 per cent. of impurities considering silicon, sulphur, phosphorus, manganese, carbon, copper, and the gases oxygen, hydrogen, and nitrogen.

Uniformity.—The method of manufacture of Ingot Iron and its freedom from impurities ensure uniformity of analysis ; this, coupled with the fact that the metal is free from slag inclusions, such as exist in even the best puddled iron, to a greater or lesser degree, ensures mechanical uniformity.

Corrosion Resistance.—The conclusion that pure iron resists rust is not merely derived from theoretical inference, but represents the definite finding of many observers of the problems of corrosion, after fully investigating generations of service evidence in the form of old hand-wrought irons, such as, for example, the Iron Pillar of Delhi. These old irons were not rustless, but they resisted rust and corrosion to a remarkable degree, by reason of their freedom from corrosion-promoting impurities.

Workability.—Ignot Iron being a dense, ductile, and uniform metal, possesses exceptional working qualities.

Welding Properties.—The superior welding qualities of Ingot Iron are due to its purity and homogeneity. Being of perfectly even texture and density throughout, it welds evenly and easily.

Paint-Holding Surface.—It has been found in service that Ingot Iron requires painting less often than other irons or steel. This is partly explained by its open-grain surface, which absorbs paint readily, and partly by the degasification which the metal undergoes during manufacture, thereby reducing to a minimum occluded gases which in course of time tend to become liberated, and cause flaking of the paint film.

Enamelling Properties.—'Armco' Ingot Iron constitutes (it is claimed) the best base known for vitreous enamelling, for the following reasons :—

It is chemically and mechanically uniform.

Its open grain surface absorbs and grips the vitreous coating.

Its degasification during manufacture reduces the risk of pinholes, blisters, and other blemishes to a mimimum.

It shows less tendency to warp than other ferrous metals during the vitreous process.

Electrical Properties.—'Armco' Ingot Iron possesses a high magnetic permeability and low retentivity. It is further a better conductor of electricity than steel; in this connection the following is the result of tests undertaken by the National Physical Laboratory :—

Resistivity

By relative mass = 5·43. By relative volume = 6·17.

(Compared with the British standards for soft copper)

This superiority in electrical conductivity renders the metal specially suitable for telegraph wire, bond wire, conductor rails, etc.

INGOT IRON can be supplied by *The Armco International Corporation* in the form of black and galvanised sheets, plates, billets, bars, shapes, wire, rods, welding rods, cold rolled strip, and welded tubes.

WROUGHT IRON.

Wrought iron is iron low in carbon content, which in course of production is in a pasty condition, owing to the fact of its being worked at a temperature too low to render it fluid. It contains a relatively large percentage of non-metallic impurities in the form of slag, which may be readily seen when the iron is examined microscopically, and which, therefore, serves, among other features, to distinguish this product from steel. The percentage of carbon in wrought iron rarely exceeds 0·15 per cent., and the total of other elements present in the metal is generally less than 0·25 per cent. Wrought iron is not appreciably hardened by quenching.

The fracture of wrought iron is fibrous in appearance and is occasionally characterised by the presence of somewhat large proportions of non-metallic inclusions.

WROUGHT-IRON (*or Mitis*) CASTINGS.

If a small amount of aluminium is added to a charge of wrought iron which has been heated until pasty, the iron immediately liquefies, and can be poured into castings having all the properties of wrought iron except fibre, and as sound as if of cast iron. These castings are called 'Mitis' castings because of their softness in contrast with cast-iron castings.

The best results are obtained by using Swedish scrap iron or English hematite iron, that is, materials containing less than 0·1 per cent. of phosphorus, which is a very injurious ingredient if present in much larger quantity. Using a mixture with poorer quality of iron, with phosphorus running up to 0·15 per cent., good results may still be obtained—that is, the castings still compare favourably with ordinary malleable castings. The following mixture for melting has been used :—Mitis scrap, 35 per cent.; hematite muck bar, 35; wrought-iron punchings, 12½; soft steel scrap (0·1 per cent. carbon), 12½, white pig iron, 3; ferro-silicon (10 per cent. silicon), 1; ferro-aluminium (6 per cent. aluminium), ½.

In general it may be said that if iron free from impurities is used very good castings are obtained; if iron is used with a large percentage of phosphorus, proportionately brittle and unsatisfactory castings result.

The ferro-aluminium used should be, for similar reasons, free from any considerable amount of such impurities as generally injure wrought iron.

PIG IRON.

Typical Analyses of Pig Iron, etc.

The following list of analyses is taken from Dr. W. H. Hatfield's book, 'Cast Iron in the Light of Modern Research.' It is published with the kind permission of the author and of the publishers, Messrs. C. Griffin & Co. Ltd.

CAST IRON.

Foundry Practice.

1.

The physical and mechanical properties of the products of the cast-iron foundry are almost entirely dependent on the condition of the carbon in these products. The carbon in cast iron can occur either in a free state, as graphite, or in combination with iron, as a carbide of iron, Fe_3C, or with iron and manganese, as a double carbide $(Fe, Mn)_3C$. Foundry practice consists almost entirely of the control of the degree of graphitisation of the carbides present in the cast iron produced.

The graphitisation of these carbides tends to increase—

(*a*) With the temperature.
(*b*) With deceleration of cooling.
(*c*) With the content of silicon, nickel, or aluminium.
(*d*) With the number of graphite nuclei in the iron.
(*e*) With the total content of carbon

Graphitisation is prohibited—

(*a*) By the presence of sulphur, oxygen, vanadium, or chromium.
(*b*) By the presence of manganese under certain conditions.
(*c*) By acceleration of cooling.

It will be seen that by the variation of the above factors an immense number of conditions can be obtained. It is in the scientific control of these that much of the success in foundry practice lies.

2. The Influence of Carbon on Cast Iron.

The strength, hardness, density of structure, etc., of cast iron are dependent almost entirely on the relative quantities of carbide and graphite in the same.

An increase in the ratio $\frac{\text{Carbide}}{\text{Graphite}}$ leads to—

(*a*) An increase in hardness, brittleness, and density of structure.
(*b*) A decrease in machinability and ductility.

The strength of cast iron reaches a maximum when the combined carbon content is between 0·80 per cent. and 1·00 per cent.; if the combined carbon content given above is exceeded a reduction in strength, which only terminates when the carbon is entirely in the form of carbide, is witnessed. The following figures, given by Howe, are of value in this connection :—

As the tensile strength increases	From less than 20,000 lbs. per sq. in.	To more than 35,000 lbs. per sq. in.	Or by more than 15,000 lbs. per sq. in.
The total carbon content decreases	from 3·69 per cent.	to 2·98 per cent.	or by 0·71 per cent.
The graphite content decreases	from 3·12 „	to 2·22 „	or by 0·90 „
The combined carbon content increases	from 0·57 „	to 0·76 „	or by 0·19 „

The above table classifies the results of an examination of 180 samples of cast iron taken without selection.

According to Dr. Stead (British Foundrymen's Association Proceedings, 1915), an increase of each 0·1 per cent. of graphite may reduce transverse strength by 2 cwts. and tensile strength by 0·8 ton per square inch.

The fusibility of the iron carbon alloys increases as the total carbon content increases up to about 4·30 per cent.; beyond this point the melting points of the alloys are raised by additions of carbon. Other effects of increased total carbon are decreased tensile strength, increased machinability and decreased chilling power. The last phenomenon is occasioned by the difficulty of retaining carbon as carbide, which naturally increases as the amount of carbon to be thus retained increases. Given suitable means for preventing graphitisation, every increase in the content of total carbon leads to an increase in the hardness of the chilled surface of the alloy in question.

The machining of cast iron containing more than 0·80 per cent. of combined carbon is practically impossible.

3. The Influence of Silicon on Cast Iron.

Silicon varies from 0·20 to 4·00 per cent. in cast iron, but rarely exceeds 3·50 per cent. or falls below 0·50 per cent. It is present in cast iron, in all probability, as silicide of iron (FeSi), which is dissolved in the pure iron, or ferrite, of the alloy. The presence of this compound tends to strengthen and harden the ferrite. Silicon, however, has the effect of rendering cementite unstable, with the result that there is a tendency towards the formation of ferrite and graphite. Starting with white cast iron, the addition of silicon up to 1·00 per cent. results in an almost proportional decrease in the chilling power of the iron. Again, the addition of silicon to white cast iron leads to an increase in the strength of the resulting irons; this factor reaches a maximum when the content of combined carbon in the alloy is between 0·80 per cent. and 1·00 per cent. As the silicon percentage is further raised so are the combined carbon content and the strength of the cast iron lowered. When the silicon content is above 2·00 per cent. its hardening effect on ferrite is noticeable, iron relatively hard to machine being occasionally improved by a reduction of the silicon content.

The presence of silicon leads to a depression of the melting-point of cast iron; in similar manner the percentage of carbon in the eutectic alloy is reduced from 4·30 per cent. to 3·40 per cent. as the percentage of silicon increases up to 3·00.

Silicon has the effect of reducing the shrinkage of cast iron.

As a means of determining the correct proportions of carbon and silicon in cast iron, the following formula has, according to Mr. F. J. Cook, been used with marked success in practical working :—

$$X = \frac{C}{4{\cdot}26 - \frac{Si}{3{\cdot}6}}$$

where

C = *total* carbon in percentage;
Si = silicon in percentage.

The elements carbon and silicon are in the best proportion when the value of X is as given below :—

For Ordinary work such as pans, grates, easily machined casting and pipes	X = 0·9 to 1
Locomotive cylinder (maximum transverse strength)	„ = 0·83
Steam, gas Diesel and hydraulic cylinders (maximum tensile strength)	„ = 0·76 to 0·82
Chilled castings	„ = 0·75 to 0·8
Acid resisting	„ = 0·85

4. The Influence of Sulphur on Cast Iron.

Sulphur combines with iron to form a sulphide having a low melting-point, which occurs in steel in the form of ovoids, oval laminæ or membranes enveloping the ferrite grains. The presence of this sulphide is the cause of red shortness.

In cast iron this sulphide may modify the properties of the alloy owing to its manner of aggregation, but it is deleterious chiefly on account of its tendency to segregate and its powerful effect on shrinkage, which it increases. Sulphur tends to restrain graphitisation, hence it increases the chilling power of cast iron and may, therefore, be termed a hardening agent. This element should, however, be employed with great caution, if at all, in this capacity, on account of the objectionable properties previously stated. The presence of sulphur makes the molten metal thick and sluggish, giving rise to blowholes, yet this element in fair proportions, say 0·12 per cent., adds considerably to the wearing properties and strength of the metal. In every case, however, sulphurous iron *must* be cast as hot as possible if trouble is to be avoided.

Manganese and silicon are employed to counteract the evil effects of sulphur. Manganese reacts with iron sulphide, with resulting formation of manganese sulphide and liberation of iron. Under certain circumstances manganese sulphide is removable from cast iron, but even when retained its effects are not so deleterious as are those of iron sulphide. Silicon, owing to its strong tendency to induce graphitisation, resists the effect of sulphur in tending to retain carbon in the combined condition; it does not remove sulphur, nor does it prohibit the shrinkage due to sulphur or reduce the tendency towards cracking.

Sulphur is frequently limited by specification to 0·05 per cent., but in the hands of experienced and careful workers as much as 0·20 per cent. can be allowed without ensuing unsoundness. If the sulphur content of an iron is to be low the conditions under which it is prepared must be such that sulphur tends to be eliminated. Hence, coke low in sulphur must be used and suitable fluxes should be employed in the furnace for removing sulphur from the metal, e.g. lime, fluor spar or manganous oxide.

5. The Influence of Manganese on Cast Iron.

Manganese and iron unite to form a series of solid solutions whose freezing-point curve lies entirely between the freezing points of the component metals. The freezing points of all the alloys of pure iron and pure manganese are below that of pure iron. The freezing point of cast iron is depressed by the addition of manganese, not only on the above account but also owing to an increase in the degree of solubility of carbon in cast iron, which is brought about by the fact that the affinity of manganese for carbon is greater than that of iron for carbon. The depression of the freezing point reaches a maximum when the percentage of manganese is about 13.

The alloys of iron and manganese (pure) are harder than pure iron. Manganese therefore would, normally, have the effect of hardening the ferrite of cast iron were it not for the fact that its affinity, firstly for sulphur, and secondly for carbon, prohibits its solution in the ferrite.

Manganese, when added to cast iron, combines in the first place with such sulphur as is present in the iron; any excess above that required for the formation of manganese sulphide unites with iron carbide, with the formation of a double carbide of iron and manganese.

The quantity of manganese required to effect the entire conversion of the iron sulphide in the alloy into manganese sulphide is considerably more than that indicated by the equation—

$$FeS + Mn = MnS + Fe.$$

Manganese sulphide is characterised by the following physical properties:—

(1) High melting point—1400° C.;

(2) Insolubility in molten iron;

(3) Low specific gravity;

all of which assist in bringing about the separation of both manganese and sulphur from the molten alloy. Rapid cooling of the molten alloy leads to the more or less complete retention of manganese sulphide in the resulting solid alloy; slow cooling assists in separating the sulphide and bringing it into contact with the slag found on the surface of the alloy when the same is, for example, in the ladle. When the metal does not remain long enough in the ladle, or is not hot enough for the above to take place quickly, the manganese sulphide will be found on the top part of the casting in the form of hard spots, which are difficult to tool. Iron sulphide is deleterious in its action upon iron and steel. Manganese sulphide, though not beneficial, is of a somewhat neutral character. Manganese is, therefore, valuable as a desulphuriser.

Such manganese as is present in cast iron in excess of that required for the transformation of iron sulphide into manganese sulphide combines with the carbide of iron to form a double carbide, as stated above. Manganese is generally considered to induce the retention of the carbon in combination. This is true, but this effect does not make itself felt until the manganese content is well above that usually found in foundry irons. Hence, though hardness is increased by the addition of manganese, the cause is not usually the retention of carbon as carbide.

On the whole it may be said that, owing to (1) the tendency of manganese to produce brittleness and coarse crystallisation, and (2) its activity as a deoxidiser, it is inadvisable to add manganese to cast iron for the sole purpose of increasing hardness and chilling power.

Manganese increases the shrinkage of cast iron.

6. The Influence of Phosphorus on Cast Iron.

Phosphorus combines with iron to form a number of compounds, of which one, that containing three molecules of iron to each molecule of phosphorus, is of common occurrence in cast iron. The presence of phosphorus effects a reduction in the melting point of cast iron and a reduction in the total carbon content of cast iron.

As the phosphorus content of cast iron is increased up to about 0·40 per cent. so is the strength of the cast iron increased. Further additions of phosphorus appear to have but slight effect on the strength of cast iron until the percentage reaches about 0·75 per cent. Above this point the alloys are liable to be brittle, and unless fluidity is more important than strength 0·75 per cent. of phosphorus should not be exceeded. For thin castings in general, which are not required to be strong, the phosphorus can be increased to 1·5 per cent. or more, but in thin castings such as automobile cylinders, which are required to withstand wear and tear, not more than 0·30 per cent. of phosphorus should be allowed, owing to the slight tendency towards segregation of high phosphide irons.

7. Semi-Steel.

Semi-steel is simply cast iron made from a furnace charge of cast iron to which mild steel or wrought iron has been added. Additions of from 10 to 25 per cent. of steel are usual, but 30 and occasionally 40 per cent. are not unknown. As steel is low in carbon, silicon and phosphorus, the final cast iron (for it is still a true cast iron) is low in these elements. The steel should be added as sheared clippings or other small pieces, but not as borings, which take up too much sulphur. Iron appears not to take up sulphur from gases, but only by direct contact with the coke, hence the air furnace gives irons lower in sulphur than the cupola and is specially suited for melting steel with pig irons. Perfectly good results are, with care, obtainable from the cupola. There is, however, a tendency for the more fluid portions of a cupola burden of cast iron and steel to run first. Hence the first tap from the cupola is generally higher in carbon content than succeeding taps.

(*The above note on semi-steel is based on a paper read before the Manchester Association of Engineers by Mr. Frank Foster, M.Sc.*)

Tests for Cast Iron.

(Abstract of paper read by Mr. F. J. Cook before the Staffordshire Iron and Steel Institute, January 20, 1917.)

Important tests which are of use as a guide to foundrymen are :—

(1) Keep's shrinkage test ;
(2) Transverse test ;
(3) Hardness test ;
(4) Casting temperature or fluidity test ;
(5) Impact test.

(1) **Keep's Test** consists of casting ½ in. square bars between iron yokes, the ends of which are 12 ins. apart. When the bars have cooled down the shrinkage is shown by the difference between the length of the bars and the gap in the yoke in which they were cast ; this is usually measured by inserting a taper graduated wedge in the gap and measuring off the dimension of the space.

This test is quite a comparative one, and when the amount of shrinkage which is associated with the most satisfactory castings has been arrived at, any deviation can be rectified by a little addition of silicon if the shrinkage becomes too high and *vice versa* when it is too low.

Under normal conditions a shrinkage of 0·183 in. = 1 per cent. silicon, and, to take the other extreme, 3·5 per cent. silicon is associated with 0·123 in. shrinkage.

(2) **Transverse Test.**—The following table gives average particulars of shrinkage, deflection and breaking load obtained with various classes of iron :—

Class of Material.	Shrinkage.	Deflection.	Breaking load.
	in.	in.	lbs.
Tough strong Iron	0·160	0·25	550
Hard „ „	0·168	0·22	630
Soft Iron	0·123	0·18	423
Mottled Iron	0·207	0·11	375
White Iron	0·226	0·08	250

from which it will be seen that to obtain a big deflection strong irons are necessary.

(3) **Hardness.**—The most handy and reliable form of test is the 'drill test,' as all other methods deal with surface hardness only. The test may be made as follows :—Cast the metal into bars 1½ in. diameter, ½ in. being shaped off one side to give a flat surface to work upon, and

move the outside skin. Drill four holes $\frac{3}{4}$ in. diameter, to a depth of 1 in., then the number of revolutions required to drill to this depth (the mean of the four holes being taken) indicates the general hardness. The angle of the drill should be ground exactly the same for each test, by means of a suitable guide on the grinding machine. It is also essential to keep the same drill for the purpose, and preferably, two drills should be used and two holes drilled with each, which minimises many discrepancies which otherwise might come in. The efficiency of drills is materially affected by the sharpness of their point, and as cast iron is often not homogeneous and may contain more or less hard spots a false result may be obtained owing to the point becoming unduly dulled by striking a hard spot in the early stages of the test. To avoid this a hole $\frac{1}{8}$ in. diameter should be first drilled, which affords clearance for the point of the drill and ensures the full cutting edge coming into operation. It is obviously necessary that the same weight be attached to the drill and also that it runs at the same number of revolutions per minute for each test.

(4) **Casting Temperature.**—Low silicon cast iron is very prone to the effects of casting temperature, and some irons employed for such purpose are also liable to liquid contraction. A handy workshop test for casting temperature with this class of iron consists in making bars of the general dimensions shown in fig. 33. When cold the bars are broken through the line AB, the condition of the fracture giving an indication of the temperature at which

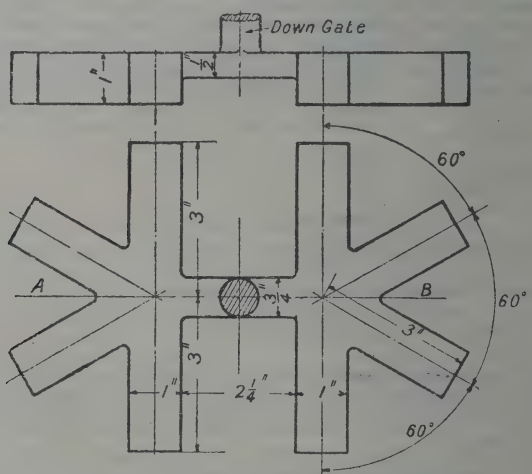

FIG. 33.

the metal was poured. Passing from the correct temperature (which is usually as hot as can be obtained from the cupola) to very low, the following fractures will be observed—perfectly solid and homogeneous, then slight whitish centre, then brown centres of varying sizes and depth of colour as temperature is lowered and then black centre; with the latter is always associated open cavities, and immediately above them is invariably found a gas hole.

For softer cast iron, which can be cast at a lower temperature without suffering the same effects as low silicon irons, a test bar in the form of a wedge is a very useful guide as to the fluidity of the metal. Dimensions of such a test-bar used by the British Chuck and Piston Ring Co. are length 9 ins., width 1 in., $\frac{3}{8}$ in. thick at the largest end tapering to $\frac{3}{32}$ at the smaller, the bars being run from the thick end.

(5) **Impact Test.**—A satisfactory test is on bars 40 mm. square (1·57 in.) supported on knife edges 160 mm. (6·3 ins.) apart, and by dropping a weight of 12 kilos (26·5 lbs.) from a height of 30 cm. (11·8 ins.) increasing the height of drop by increments of 5 cm. (1·9 in.) until such times as the sample breaks, the height at which the bar eventually fractures being taken as the impact figure. Attached to the weight, in such a manner as to strike the bar parallel to the supporting knife edges, and the centre of same, is another knife edge. The face of all the knife edges should be rounded $\frac{1}{16}$ in. radius.

A result of 55 cm. (21·5 ins.) is none too high for the work named, although this is quite a severe test. The maximum attained, as far as is known, has been 80 cm. (31·3 in.).

Analyses and Mechanical Properties of Cast Iron.

E—modulus of elasticity.

The above is taken from the practice of a large German engineering firm as published in the German technical press in 1908. The test bars are round, of the varying diameters stated: all cross-breaking loads being on one metre (39·37 ins.) span.

STEEL.*

The term 'steel' is applied in a general sense to those alloys of iron and carbon whose carbon is present entirely, or almost entirely, in the combined condition and whose total carbon content does not exceed 2·00 per cent. In a special sense the term is applied to alloys of iron and carbon with elements which are generally in excess of the carbon and whose presence considerably modifies the resulting alloys; such alloys are generally named 'special steels.'

The pure alloys of iron and carbon are unknown commercially. Steel is always contaminated by some or all of the elements—manganese, silicon, sulphur and phosphorus. The effect of these elements on steel is considered below.

1. THE INFLUENCE OF CARBON ON THE PROPERTIES OF STEEL.

Carbon exists in steel in various forms and combinations, the following being those most generally recognised:—

(*a*) Free Carbon.

(1) GRAPHITIC CARBON.

Rarely found in steels, as it is generally produced only when the alloy has taken up more carbon than it can retain in solution on solidification—about 2 per cent.

(2) TEMPER CARBON.

Present in steels containing upwards of 1·0 per cent. carbon, which have been heated to redness. It is mainly found in white pig irons that have been subjected to annealing and tempering.

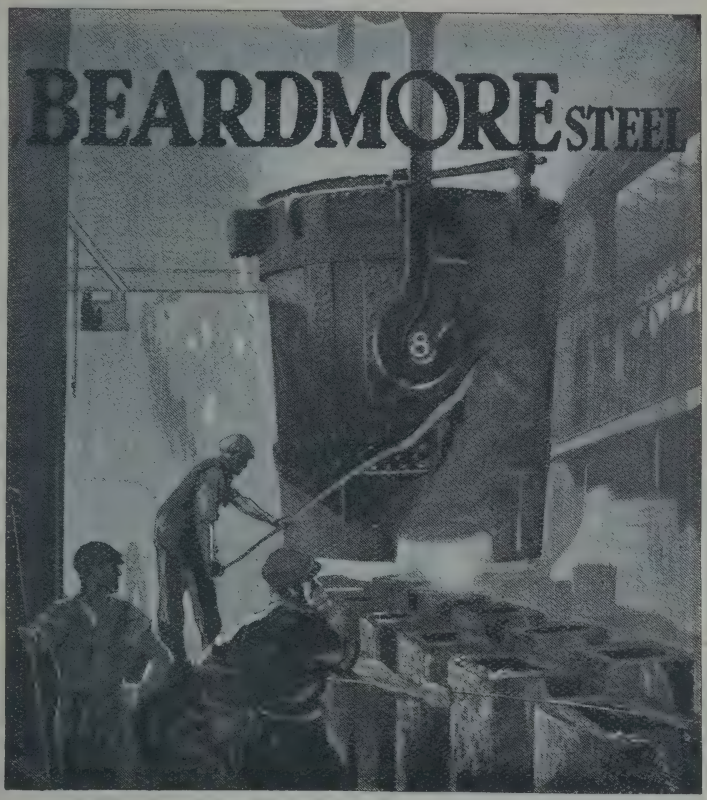
(*b*) Cement Carbon.

The carbide Fe_3C, which is known as 'cementite,' when considered as a microscopical constituent of steel. It exists in unhardened steels. The carbide is soluble in nitric acid of 1·20 sp. gr., giving a brown solution, which is of value in the estimation of the carbon percentage of steels.

(*c*) Hardening (Solution) Carbon.

Occurs in quenched steels, of which the tenacity, hardness and brittleness increase, within limits, as the percentage of hardening carbon in the steels increases.

* See also 'Tool Steel,' p. 1099.



STEEL SHEETS, SHIP AND BOILER PLATES AND SECTIONS

These essential products are produced in large quantities at the Steel Works of Parkhead and of Mossend

PARKHEAD LONDON OFFICE 36 VICTORIA ST. S.W.1. GLASGOW

Stead states that 'the influence of carbon on the properties of normalised steel,' i.e. steel that has been heated to a temperature above that of all its critical points and cooled in air 'containing less than 0·90 per cent. carbon, approximates to the following average :—

EFFECT OF 0·1 PER CENT. CARBON.

Yield point is raised	1·78 tons sq. in.
Maximum stress is raised	4·18 ,,
Elongation is reduced	4·33 per cent.
Reduction of area is reduced	7·27 ,,

The figures represent material with only small quantities of manganese.'

Sauveur suggests the following formula for the average maximum stress of hypo-eutectoid (containing less than 0·83 per cent. carbon) steel, containing from 0·20 per cent. to 0·80 per cent. manganese :—

$$T = 22{\cdot}3 + 4{\cdot}02\ C \text{ (tons sq. in.)},$$

where T = Maximum stress.
and C = Carbon content.

For hyper-eutectoid steel (containing over 0·83 per cent. carbon) he suggests the following :—

$$T = 63{\cdot}4 - 9{\cdot}2\ C \text{ (tons sq. in.)},$$

which formula must, however, be employed with considerable judgment. (See also p. 2540.)

The maximum degree of hardness of steel is reached when the carbon content is 0·90 per cent.

2. THE INFLUENCE OF SILICON ON THE PROPERTIES OF STEEL.

Iron and silicon combine to form a compound, iron-silicide (FeSi), which, in all probability, forms a series of solid solutions with iron. It is, then, in the form of a solid solution that silicon occurs in steel.

The influence of silicon on the properties of steel increases with the percentage of carbon. In the case of low carbon steel silicon up to 1·75 per cent. increases the yield point and tensile strength without reducing the ductility; beyond this percentage increase of tenacity is accompanied by a serious loss of ductility. The silicon content of carefully manufactured mild steel rarely exceeds 0·20 per cent. Generally speaking, high carbon steels are benefited by the presence of silicon.

Silicon produces soundness in cast steel and is largely used in the manufacture of basic open-hearth steel. The effect of silicon on the mechanical properties of steel is somewhat variable and no definite figures are, therefore, quoted in this connection.

3. THE INFLUENCE OF MANGANESE ON THE PROPERTIES OF STEEL.

Manganese is present in steel owing to its premeditated addition—made with a view to deoxidise the decarburised metal in the steel furnace. It also acts as a 'desulphuriser,' in the sense that it modifies the action of sulphur on steel. Provided the manganese content of a given steel is sufficient to retain the sulphur therein almost entirely, if not entirely, in the form of manganese sulphide, the deleterious effects of sulphur will be avoided. This statement does not mean, however, that the quantities of manganese and sulphur that may be present in a given steel are unlimited.

Manganese combines, in the first instance, with the sulphur in the steel (see note on Manganese in Cast Iron). Any excess of manganese over the amount required to form manganese sulphide combines with some of the carbon to form manganese carbide (Mn_3C).

The effect of manganese on the physical properties of steel is not known with certainty. Harbord considers that for mild steel and rail steel the less the content of manganese above that required to ensure solid ingots and freedom from red shortness the better. The manganese content of mild steel for boiler plate and structural work should be limited to 0·60 per cent. The presence of 1·00 per cent. of manganese in medium high carbon steel does not induce brittleness; in high carbon tool steels not more than 0·50 per cent. should be permitted, owing to the liability to fracture during the process of quenching incurred thereby. It seems likely that the mechanical properties are varied too slightly and too vaguely as to be of note if manganese be present in quantities of less than 1·25 per cent.

4. THE INFLUENCE OF SULPHUR ON THE PROPERTIES OF STEEL.

Sulphur occurs in steel in combination either with manganese or with iron. The compound of manganese and sulphur has a high melting point, low specific gravity, and occurs almost always in the form of globules or ovoids (*Arnold*). It may seriously affect the properties of steel if present in large quantities, but its presence is not nearly so deleterious as is that of iron sulphide. The latter compound has a low melting point and can occur not only in the form of globules or ovoids

but as meshwork surrounding the crystals of ferrite in steel. The low melting point of this compound is generally considered to be the cause of the red shortness of sulphurous steels, which red shortness is of course, considerably aggravated when the iron sulphide surrounds the crystal grains.

The above serves to show that manganese modifies the effects of sulphur and, since manganese has a greater affinity for sulphur than has iron, the manganese content of steel is frequently adjusted with these modifying effects in view.

Sulphur appears (i) to reduce the yield point, maximum stress and percentage elongation of steel, (ii) to increase the percentage reduction of area and the resistance to shock and (iii) to increase the cutting freedom of steel during machining. Certain steels specially noted for the last feature are known having a content of sulphur of 0·15 per cent. Such a sulphur content is out of the question for steel that is to be welded or to be manufactured into rails or material for structural purposes. Steel that requires to be welded should contain not more than 0·06 per cent. of sulphur, while such as is to be employed for rails or constructional work should have an upper limit of 0·08 per cent. of sulphur. It is advisable when consideration is taken of the sulphur content of a steel to take note also of the percentage of manganese in the same.

5. The Influence of Phosphorus on the Properties of Steel.

The small amount of this element usually present in steel is held in solid solution by the iron as phosphide of iron (Fe_3P). Phosphorus is supposed by some to enlarge the grain of steel, thus inducing the dangerous characteristic of cold-shortness to steel.

The effect of phosphorus becomes more noticeable as the carbon content of steel is raised. In low carbon steels not more than 0·10 per cent. is, as a general rule, allowable, while for most purposes—e.g. constructional steel—0·06 per cent. should not be exceeded. Certain steels contain quantities in excess of 0·10 per cent., but owing to the liability of steels containing much above 0·08 per cent. of this element to failure under shock, the last figure may be considered as a safe limit for most purposes. In high carbon steels the effect of phosphorus is much more noticeable, an increase of 0·01 per cent. being quite noticeable (*Howe*) in 1·00 per cent. carbon steel. A limit of 0·04 per cent. is considered advisable in the latter steels.

Stead quotes the following figures for the effect of 0·10 per cent. of phosphorus on the mechanical properties of steel :—

Yield point is raised	2·5 tons per sq. in.
Max. stress is raised	2·4 ,,
Elongation is reduced	0·7 per cent.
Reduction is reduced	1·5 ,,

The specific work required to produce rupture decreases as the content of phosphorus increases.

6. The Tenacity of Steel as affected by the above Elements.

McWilliam quotes the following formula :—

$$T = 38000 + [800 + 4(C - 20)]\,C + 1205 + [100 + 2\,(C - 20)]\,Mn + 1000\,P$$

as representing the maximum stress value of normalised basic steel in pounds per square inch. There is a difference between steels of acid and basic origin such as renders the formula of little value for purposes of determining the properties of steel of the former type.

7. The Influence of Nickel on the Properties of Steel.

The following are results of tests of nickel steel made by the St. Jacques Steel Works :—

1. 2 to 5 per cent. of nickel. Resistance increases with percentage, especially when carbon content is low. When carbon reaches 0·50 per cent., nickel has little influence. Forges and rolls well. When hardened, ratio of elastic limit to ultimate resistance is very great.

2. 10 to 20 per cent. nickel. Resistance increases with percentage of nickel. An addition of 0·10 per cent. of carbon increases ultimate resistance from 19 tons to 41 tons. With 2·0 per cent. nickel resistance is 69 tons. With increased carbon up to certain limit, over 127 tons can be obtained. Resistance with 10 per cent. nickel decreases when carbon is 0·50 per cent. These steels do not harden much, and do not harden at all when the carbon is higher than 0·10 per cent.; 20 per cent. nickel steel never hardens. All are very brittle. They forge and roll well, but when containing more than 0·10 per cent. carbon they cannot be machined.

3. 20 to 25 per cent. of nickel. Elastic limit, as well as ultimate resistance, is low. They have great elongation, and are nearly free from brittleness. When forged at a low temperature without annealing, elastic limit increases notably, and has reached 35 tons with an ultimate resistance of 51 tons, and an elongation of 25 per cent. With less than 1 per cent. carbon the steel can be easily forged and rolled. With 1 per cent. of carbon, can be forged between 500° and 1,000° with light blows. Machining is difficult, but not impossible.

An ultimate resistance of 40 tons can be obtained from 3 per cent. nickel steel with ·175 per cent. of carbon, when to obtain this strength in ordinary steel would require at least ·50 per cent. of carbon, sufficient to make the material so brittle as to be unreliable.

In general, the elastic limit of nickel steel is above 50 per cent. of ultimate resistance.

Nickel steel cannot be machined as easily as low carbon steel.

NOTES ON STEEL SPECIFICATIONS.

(*Frank Foster, M.Sc.*)

Steel Forgings.—These should be of Siemens-Martin open-hearth make, and in this country it is usual to specify acid steel. In Germany and America basic steel is usual.

The test bars should conform to British standards or the value of the elongation is misleading. The parallel portion of a test piece should extend not less than one-quarter of the diameter beyond each gauge mark. The test piece may conform to one of the following after machining:—

Diam. 0·564 in., area 0·25 sq. in., gauge length 2 ins.
Diam. 0·798 in., area 0·50 sq. in., gauge length 3 ins.
Diam. 0·977 in., area 0·75 sq. in., gauge length 3·5 ins.

The following are suitable test requirements, all forgings being well annealed after leaving the hammer or being rough machined:—

Forging.	Tensile, tons sq. in.	Elongation per cent.
Crankshafts and general	28–32	27–23
Piston rods	33–37	22–20
Connecting rods and pins	30–35	25–20

The carbon content varies from 0·2 to 0·35 per cent., according to tensile strength; 0·3 per cent. carbon giving, according to H. Brearley, 34 tons tensile and 30 per cent. elongation with 52 per cent. reduction in area.

Nickel Steel.—It is usual to specify that nickel steel shall contain 3·5 per cent. of nickel, but it may fall as low as 3 per cent. It is not usual to make mention of heat treatment, although this enables the qualities to be improved. Forgings of this character, with 3 to 4 per cent. nickel, are chiefly used for heavy connecting rod bolts and important valve spindles; also, at times, for piston rods. Typical tests results are 35 to 48 tons tensile, and 18 to 22 per cent. elongation.

According to H. Brearley and others the most reliable material for rapidly applied shock loads, of which an aeroplane engine valve with spindle is a good example, is a 25 per cent. nickel steel.

20 per cent. of nickel renders steel non-corrodible.

Nickel-Chrome Steel.—Occasionally engine builders require a specially strong, tough, and hard steel, say for pins under severe loading. It is perhaps best in these special cases to put oneself in the hands of a good steel firm, but it may be of interest to note that nickel-chrome steel is much used in such cases. It is air-hardening and can thus be cooled slowly to avoid contraction stresses after heat treatment. According to Brearley (Manchester Association Engineers, October 1914) the tensile strength varies from 42 to 130 tons, and the elongation from 30 to 10 per cent. with from 66 to 35 per cent. reduction in area, according to the heat treatment.

American Forgings.—For large forgings tensile strength not less than 75,000 lbs. (33·5 tons); elastic limit not less than 40,000 lbs. (17·8 tons); elongation not less than 20 per cent. in 2 ins. with a reduction in area of 45 per cent. Forgings to contain about 0·4 per cent. carbon and not over 0·04 of sulphur or phosphorus. To be thoroughly annealed.

Cast Steel.—Steel castings are made by firms specialising in the business and rarely by the engine-builders. As a rule a very vague specification is drawn up and no tests are called for.

Of whatever quality, it is important that steel castings should be well annealed. According to Prof. Arnold, about 180 hours total time is required for this.

Test bars should be cast on the work and machined before testing.

For hydraulic and steam or gas engine work the tensile strength should lie between 28 and 32 tons per square inch, with an elongation of 20 per cent. or over, on a standard test piece. A test piece 1 in. wide by ¾ in. thick should stand bending through an angle of 90° with an inner radius of one inch.

For heavy gear wheels the above tests may be specified, but better wearing qualities are obtained with a higher carbon content, giving a tensile strength of 35 to 40 tons per square inch and an elongation of about 12 to 15 per cent.

Chemical tests are seldom specified and are rarely necessary, provided the mechanical tests are satisfactory. The usual run of castings contain about 0·3 per cent. carbon.

Bar Stock.—Rolled and drawn bars, both bright and black, are largely used in engine construction, and the following notes are based on the British Standard specification. Two qualities, 1 and 2, are to be as follows:—

Quality.	1.	2.
Tensile, tons, not less	28	35
Elongation, per cent.	14–17	12–14·5
Carbon, per cent.	0·25	0·40
Manganese	0·85	1·00
Silicon	0·20	0·20
Phosphorus	0·06	0·06
Sulphur	0·06	0·06

The test pieces must be cut from the stock bars and not machined. Bending tests are advisable, especially with cold drawn and reeled bars, as these do not prove perfectly reliable in practice. (*Frank Foster, M.Sc.*)

Cobaltron Steel Alloy (Patent).

This alloy (patent) introduced by Messrs. Darwin and Milner, of Sheffield, is made by adding cobalt to chromium-carbon steel. The maximum temperature necessary for the hardening is 1000° C. (tungsten steel requires from 1250° to 1350° for the best results) and hardening is said to be satisfactory when the steel is allowed to cool naturally in still air. Analysis of cobaltron shows that the following elements approximate to the amounts stated below:—

Carbon	About 1·5 per cent.	Molybdenum	About 1·25 per cent.
Cobalt	,, 2·25 ,,	Tungsten	,, 0·25 ,,
Chromium	,, 11·0 ,,		

'Heenan' Oil Coolers for Heat Treatment of Steel.

The continuous introduction of hot steel into oil quenching tanks naturally heats up the oil, which retains heat for a long time, and rapidly becomes too hot to permit of the process being carried on.

Owing to the poor heat conductivity of oil, such arrangements as water-jacketing the tank or inserting pipe coils through which water is circulated are ineffective, the cool surfaces affecting only that portion of the oil in immediate contact therewith, while allowing the main body to remain over-heated.

The 'Heenan' system of oil cooling is to extract the hot oil by means of a suitable centrifugal pump, and pass it through a 'Heenan' oil cooler before returning it to the quenching tank. This oil cooler is built up on lines similar to those of the water cooler described on page 1235. In effect, oil is spread over a large cooling surface with which cool air from the surrounding atmosphere is then drawn into contact. Circulating water is not used.

This machine has been applied amongst other purposes to quenching processes in connection with the hardening and tempering of gun tubes, rifle barrels, steel tools, gear wheels, springs, aeroplane engine parts, etc.

Chromium Plating of Steel.

Using solutions of 3 grams per litre chromium sulphate and 200–400 grams per litre chromic acid, good adherent deposits of chromium on iron can be obtained. The cathode current density range for good deposits should be from 100–150 amperes per sq. ft.

Best results are obtained using Sargent's solution of 3 grams per litre chromium sulphate, 245 grams per litre chromic acid, and a current density of 125 amperes per sq. ft., the anodes being of chromium.

Chromium-plated iron and steel have a hard, bright, silver-like surface, resist atmospheric corrosion indefinitely, and are resistant to the action of fumes of nitric acid, hydrogen, sulphide, and ammonia. They also resist the corrosive action of molten tin, zinc, and brass. Steel does not lose its temper during chromium plating.

(*Chemical and Metallurgical Engineering, April* 21, 1924.)

CASE-HARDENING.

The case-hardening of steel is dependent upon the fact that above certain temperatures the affinity of iron for carbon is so great that when iron or steel is heated at these temperatures in contact with suitably chosen carbonaceous materials ready absorption of carbon supervenes. The quantity of carbon that can be absorbed by iron or steel under the above conditions varies according to the following factors—

1. The composition of the iron or steel.
2. The temperature at which the process is conducted.
3. The length of time during which the process is continued.
4. The nature of the carburising material.

The Composition of the Iron or Steel.

Case-hardening, in the accepted sense, is rarely practised on steel containing more than 0·20 per cent. of carbon or 0·40 per cent. of manganese. The process is stated by Guillet to be hindered by the presence of nickel, silicon and aluminium, and hastened in the presence of manganese, tungsten, chromium and molybdenum.

The Temperature at which the Process is Conducted.

The process is best conducted at temperatures above the critical range of the iron or steel treated. The usual temperatures for carburisation vary from 900° C. to 1000° C. The higher the temperature of carburisation the greater the rate of absorption of carbon and the deeper the effect of absorption.

The Length of Time during which the Process is Continued.

This factor can only be determined by experiment. It is generally considered that the best results are obtained when the carbon content of the surface layers of the case-hardened material are of eutectoid composition (about 0·90 per cent. C).

The Nature of the Carburising Material.

The carburising material may be either solid, liquid, or gaseous. Solid materials are employed more generally than are liquid or gaseous materials.

Solid Case-hardening Materials.

For the purpose of obtaining deep 'cases' the articles to be hardened are packed in a suitably designed box with solid case-hardening substances or mixtures of substances, of which the following are examples :—

Charcoal (animal or wood).
Charred leather.
Crushed bone or horn.
Barium carbonate 40 per cent. and charcoal 60 per cent. (Caron's mixture).
Charcoal (wood) 95 per cent. and soda ash 5 per cent.
Charcoal (wood) 90 per cent. and common salt 10 per cent. (Guillet).

As case-hardening composition is bought by weight, and is required to fill up the case-hardening boxes, the specific gravity is an important consideration. The speed of conduction of heat through various depths of carburising material requires determining by experiment. A good case-hardening material should not diminish in volume appreciably during the carburising operation, and should be free from sulphur and phosphorus.

The box should be of plate iron not less than $\frac{1}{8}$ to $\frac{1}{4}$ inch thick. The lid of the box has two holes pierced in it for drawing testing-pieces out if required. For small articles a piece of wrought-iron tube, plugged or capped at one end, may be used; the other end is closed by a second plug fastened with an iron pin passing through it and the pipe, the whole being luted with fine clay. The articles being previously finished, except polishing, are put into the box in alternate layers with the carburising mixture, commencing at the bottom of the box with carburising mixture to the thickness of about $\frac{3}{4}$ inch; upon this a layer of the articles is placed, then another of carburising mixture about one-third the thickness of the first, and so on until the box is nearly full, finishing with carburising mixture about the thickness of the first layer, leaving room every way for the expansion of the articles by the heat, otherwise they will bend each other in the box. The packing completed, the lid is put on, the box luted and placed in a suitable furnace. The contents of the box require to be very gradually and uniformly heated to redness, and retained at this heat for the period required for the depth of caburisation desired. The depth of carburisation depends on the length of time the temperature is kept up. For testing pieces plain pieces of the same kind of iron as the articles may be used. They require to be brightened, and are placed, at the time of the packing of the box, in the central part, in such a manner that they may be readily pulled out through the holes in the lid, either by a piece of iron wire attached or by being made long enough to project through the holes, so that they may be gripped with pliers; the holes are luted the same as are the other parts. When the articles are sufficiently carburised the box is drawn from the fire, the lid taken off, and the contents are immersed in pure cold water; taken out when

cold they are ready for polishing. To prevent rusting, the articles may be dried by riddling in a sieve with dry sawdust, after which they are wiped with a greasy cloth. If the articles be immersed in oil instead of water they will be much tougher but less hard, though sufficiently so for some purposes. It is not necessary to immerse them direct from the box, as it answers equally as well to allow them to remain in the box till cool, and then reheat then in an open fire and immerse them separately.

When the case-hardening is required to terminate at any particular part of the article, the part needed to be soft may be bound with iron wire and cased with loam. This prevents the iron from absorbing carbon at that part. The loam requires to be gradually dried on the article previous to putting in the box, otherwise it will crack. 'Harbee,' in a letter to *Engineering* (August 15, 1913), states that, in order to 'stop off' that portion of the article required to be kept soft, a thin coating of copper (one thousandth of an inch in thickness is sufficient) electrolytically deposited will effectually resist any attack of the case-hardening material. After case-hardening the film of copper can be readily removed by the aid of a pocket knife. Copper plating, however, is expensive. Another method is to cover the part needing protection with a copper tube (this is the most satisfactory method when the shape of the work will allow the use of the tube) or to paint it with a protecting paint (paint can be made from china clay and blacklead or from sodium silicate and sand). A frequent procedure is to carburise an object and allow it to cool in the box, finally machining off the carburised portion before quenching wherever it is desired to keep the surface soft. It is of course necessary to leave sufficient metal on the object before carburising in order to ensure complete removal of all carburised metal before quenching. With long objects, one end of which requires hardening while the other is to remain soft, it is possible to carburise the entire length, then reheat and quench one end only, allowing the other end to cool in air.

For the purpose of superficial case-hardening it is necessary only to heat the iron or steel to be treated to redness, to sprinkle one or other of the following finely powdered compounds or mixtures on the surfaces to be hardened, and to plunge the iron so treated into pure cold water. This method is simple and speedy, but the case obtained is insufficiently thick to resist much wear.

Potassium cyanide.

Potassium ferrocyanide.

Potassium ferrocyanide and potassium bichromate.

Sodium ferrocyanide 90 per cent. and anhydrous sodium carbonate 10 per cent.

Sodium ferrocyanide 80 per cent., anhydrous sodium carbonate 10 per cent., and potassium ferrocyanide 10 per cent.

Liquid Case-hardening Materials.

The immersion of steel articles in a bath of molten potassium cyanide (the fumes of which are of a highly poisonous nature) heated to 850° C. results in the formation of very hard but shallow cases.

Gaseous Case-hardening Materials.

The following gases have been employed for case-hardening iron and steel—illuminating gas, carbon monoxide, acetylene and petroleum vapour. All, according to Brearley, are supposed to be more effective if they are led through a solution containing ammonia, or otherwise are partly saturated with ammonia gas before entering the furnace. By increasing the pressure of the gaseous mixture it is possible to increase the rate of carburisation.

Thermal Treatment of Case-hardened Materials.

Quenching.—If the quenching takes place directly after the carburising operation, the resulting product is liable to possess a coarse structure in both the core and the case. In order to improve the structure it is better to allow the work to cool in the box after cementation, and then reheat it in a separate operation. The reheat may be made bare in the furnace, but with large objects which take long periods to obtain the desired temperature it is advisable to protect them from decarburisation by covering them with charcoal or old case-hardening mixture. This second reheat is most satisfactory at temperatures of about 780° to 820° C. It is claimed that very good results may be obtained by reheating twice, first with a view to refining the core and secondly to refine the case. A sample treatment of this description is :—

1. Carburise at 900° C. and allow to cool in box.
2. Reheat at 900° C. bare, and allow to cool in air.
3. Reheat bare for 20 minutes at 810° C. and quench in water.

Another common treatment which is said to yield fine core structures is to reheat twice and quench after each reheat, e.g. :—

1. Carburise at 920° C.
2. Reheat to 900° C. and quench in oil.
3. Reheat to 810° C. and quench in water.

In order to refine the cores of case-hardened articles it is advisable to heat the same to at least 875° C. (unless the carbon content of the core is above 0·20 per cent.) and quench. This treatment refines the core of the article but coarsens the case, hence it is necessary to reheat to a temperature somewhat above the critical range corresponding to the carbon content of the case (775° C. to 825° C.), subsequently quenching the article in water, or in oil.

Quenching in water results in a much more rapid cooling than oil quenching; the former is necessary for ball races, cams, and all parts which have to be subjected to hard wear and require extreme hardness (80 to 90 scleroscope). Oil quenching of correctly carburised mild steel results in a hardness of 50 to 70 scleroscope. Small objects cool more rapidly, and therefore become harder than large objects undergoing the same treatment.

Tempering of the quenched articles still further improves the properties of the same.

Annealing.

To Prevent Oxidation and Scaling during Annealing.

It is sometimes desirable that steel should be thoroughly annealed without any oxidation and scaling whatever taking place. The most popular method of doing this is to simply pack the stampings in sand, but this method is not good, because, unless the sand be extremely fine, air will eventually percolate through the grains of the sand. The following method has been found to give first-grade results, and steel articles may be heated for many hours and come out with a perfectly bright surface. The packing mixture consists of finely powdered burnt lime containing a trace of powdered charcoal. A thick layer of lime is tightly rammed down in the bottom of a box, similar to those used for case-hardening purposes. The articles are placed in position on the lime and a further layer of lime is tightly rammed down on top of them, with a sprinkling of powdered charcoal on top of the lime. Several layers of articles may be packed in this way till the box is full, when it is covered with a lid and luted up with clay. Although this process is not so quickly performed as some, it gives excellent results.

If such articles as small die castings or brass or bronze extruded sections require to be annealed, the articles are dipped in a saturated solution of borax or boric acid in methylated spirit. The spirit evaporates at once, and leaves a sound protective coating of the solid which coagulates on heating and effectively resists the deleterious action of oxidising and other gases at tempera tures up to some 750 deg. C., which is as high a temperature as is usually employed for the general heat-treatment of non-ferrous metals and alloys.

The coating of the borax or boric acid is so extremely thin that there is usually no necessity to remove it after heating, but should this be necessary, hot water will suffice.

(*Met.*, '*Machinery.*')

For Welding and Cutting, see page 2587.

CORROSION OF METALS.*

Corrosion of Iron.

Professor T. Turner in his book on 'Iron' says the results of the experiments of the Admiralty Committees which issued reports in 1877 and 1880 led to the conclusion that common iron was less affected by corrosion than best Yorkshire iron, which is in accordance with the statement of Gmelin that phosphorus diminishes corrosion in iron.

In these experiments :—

Common iron resisted corrosion better than Yorkshire iron 9·6 per cent.

Yorkshire iron resisted corrosion better than mild steel, 16 per cent.

In another series of experiments conducted by D. Phillips, in Cardigan Bay, and lasting for seven years, it was found that the average corrosion of mild steel during the whole period was 126 per cent. more than wrought iron.

The independent experiments conducted by T. Andrews also showed that wrought iron corroded less rapidly than mild steel when the cleaned metallic surfaces were exposed to the action of the water.

Iron rusts very quickly when immersed in water from bogs and marshes which contain a large quantity of carbonic acid, derived from decayed vegetable matter.

Iron does not rust in dry air.

Iron subject to vibration rusts slowly. Railway rails in running roads where trains are passing frequently rust much less than those in sidings which are little used. Rails which are kept in reserve and not in use rust more quickly still.

Thin iron rusts more rapidly than thick, because the expansion and contraction owing to changes of temperature throws off the scales more quickly.

In moist air, steel rusts more rapidly than wrought iron, and wrought rusts more rapidly than cast. (See table, page 270.)

Cast iron in salt water becomes in time soft and porous. The smoother the surface of iron the more slowly it rusts.

Once rust forms the process goes on more rapidly; rust being a porous substance it absorbs moisture and acids from the atmosphere.

* See also page 270.

Protection of Iron from Rust.

The types of coating applied to iron and steel for their protection may be classified as follows :—

1. Adherent coatings. 2. Compound coatings.

1. Adherent Coatings.

These may be metallic or non-metallic in character. Of methods for the production of metallic coatings of this type the following are the most noteworthy examples :—

(*a*) Galvanising.—This is a process which has for its object the coating of the material with zinc. Two processes, known respectively as hot galvanising and electro-galvanising, are employed for attaining the desired object.

Hot galvanising consists in the immersion of the object to be protected from corrosion in molten zinc or spelter, the surface of which is largely protected from oxidation by a supernatant layer of ammonium chloride. Modifications of the simple process briefly described in the last sentence are known under the following names, Winiwarter's process, Kufler's process, Bedson's process, Reese's process, Porter's process, etc.

The amount of zinc on modern galvanised sheets varies from 1 to 2·5 oz. per square foot coated. The coating generally contains from 0·25 to 1·00 per cent. of lead and from 2 to 6 per cent. of iron.

The most obvious disadvantages of galvanising are two in number: first, the iron or steel coated has to be raised in temperature for the desired effect to be attained; second, a layer of weak zinc-iron alloy forms at some point intermediate between the true zinc layer and the iron or steel upon which it is designed to rest. This thin lamina of weak alloy, mainly the compound $FeZn_7$, may be insufficient in a majority of cases to cause trouble, but a serious reduction in tensile strength is frequently brought about as a result of the presence of this weak material in fine gauge wires and sheets.

Electro galvanising (cold galvanising) consists in the deposition of zinc electrolytically upon the object to be protected from corrosion, a soluble zinc salt being employed as electrolyte. The most important process under this head is that of S. Cowper-Coles, wherein an electrolyte of zinc sulphate is used, the electrolyte being continuously regenerated by circulation through tanks containing zinc dust. The methods of cold galvanising associated with the names of Heathfield, Powick, Pottkoff, Rawson, Wagner, Walker, etc., are worthy of note. Particulars of their processes are obtainable in the technical press.

The electrolytic process leads to the formation of an intermediate lamina of only minute thickness. In this particular the coating produced by the electrolytic process is an improvement upon that obtaining as a result of hot galvanising. It is, however, porous, and in this respect is inferior to the zinc coating produced in the dipping process. No marked superiority can be claimed for either of the processes.

Electro galvanising has made great progress during the past few years, and may now be regarded as an efficient method of rustproofing. By its means a wide range of articles may be coated with a film of zinc which, while ample to protect from oxidation, does not affect ductility or tensile strength. The fact that perfect cleanliness must be achieved before the adherence of zinc can take place prevents dirty patches on the article becoming coated. The main cause of failure with hot galvanised work is the covering up, through the surface tension of molten spelter, of dirty or scaly places, which blister or otherwise fail in a comparatively short time. A commercially protective coating is obtained with a deposit of 4 oz. per square yard of surface. The deposit is practically pure, lead being the chief adulterant, then only in a fraction per cent. Accurately machined parts can be assembled after coating, this overcoming a difficulty ever present in the past. Hot galvanised bolts must have the thread bared before the nut will fit. Cold galvanising coats the thread so that the configuration is not destroyed, and unless the nut is a very tight fit the zinc remains on the thread and thus protects it against corrosion.

Admiralty specifications require a deposit of 0·86 oz. of electro-deposited zinc per sq. foot of surface of the articles treated.

(*b*) Tin plating is a process similar to hot galvanising, tin being the coating metal. The protection afforded to iron and steel by tin is less effective than is that of zinc.

(*c*) Terne plating consists of the coating of the material to be protected with an alloy of lead containing from 50 to 75 per cent. of tin (generally 70 per cent. tin).

(*d*) Lohmanising—in this process the metals to be protected are (i) pickled in an acid bath, (ii) dipped into a salt bath which deposits a metallic salt over the entire surface of the body, (iii) immersed in a bath of molten alloy of zinc, lead and tin heated to a temperature of from 500 to 600° C. The composition of the tin-lead-zinc alloy is varied to suit the material being treated.

(*e*) Electro-plating—the coating of iron and steel electrolytically with copper, nickel, etc., is well known.

(*f*) Copper 'clothing'—the casting of copper round or the welding of copper to steel and the rolling of the resultant material to the required shape and dimensions has been practised, e.g. Monnot process, Willis process, etc. (vide *Iron Trade Review*, vol. li. 479).

(*g*) Nickel 'clothing'—processes similar to the Monnot and Willis processes have been successfully applied to the coating of iron and steel with nickel and cupro-nickel.

(*h*) Metallic spraying—the application of liquid metal in finely subdivided form by a spraying machine has been accomplished by M. U. Schoop, whose process, 'the Schoop process,' allows of the coating of iron or steel with an adherent layer of tin, lead or zinc, the material being coated remaining meanwhile at the ordinary temperature. The material under treatment must be scrupulously clean if adhesion of the finely-divided spray is to be perfected (vide *Metal Industry*, vol. xvi. 41).

Of methods for the production of non-metallic coatings of this type the following are the most noteworthy examples :—

(*a*) *Painting* (see page 2623)—The term 'paint' is applied to such substances as are employed as protective coatings in liquid form, but which under the action of oxygen dry and finally become hard and resistant. Paints are composed of :—

(*i*) solid substance in a state of fine division (pigment);
(*ii*) liquid in which the solid is held in suspension (vehicle); and, frequently,
(*iii*) salts of manganese, etc., for the purpose of hastening oxidation of the vehicle (drier).

Friend (*Carnegie Schol. Mem.* vol. ix. 1918, 117) summarises the conclusions respecting painted ironwork exposed to atmospheric corrosion as follows :—

1. The practical value of acceleration tests is shown to be very small in the present state of our knowledge. Reliable results can only be obtained from tests carried out under conditions closely resembling those required in practice.

2. Addition of pigment to oil increases the efficiency of the latter as a protective paint until a maximum is reached. After this, further addition of pigment causes deterioration. The best results are obtainable from paints possessing as high a percentage of good oil as is compatible with good body and any other working property that has to be considered.

3. Linseed oil on setting expands by some 3·3 per cent.; this is the primary cause of crinkling. Further oxidation causes a decrease in volume; this in time leads to cracking.

4. Linoxyn is permeable to moisture. The permeability is reduced by heating in absence of air, the oil increasing in density, viscosity, and molecular weight.

5. Polymerised linseed oil affords a better protection than raw oil when used as a paint vehicle.

6. The functions of a pigment are to toughen the film and render it less permeable to water vapour and oxygen. It also reduces the expansion of the oil on setting and thus minimises the tendency to crinkle.

7. A thick coat of paint protects the underlying metal more efficiently than a thin coat, provided the coat is not so thick that running or crinkling takes place.

8. The very best results are obtained by multiple coats. Two thin coats are better than one thick one of equal weight.

9. Thinners enable thin coats of paint to be applied. Turpentine leaves a very slight residue behind upon evaporation, but its effect on the efficiency of the paint is small.

10. Other things being equal, the most permanent paints are those containing black or red pigments, since these absorb the shorter rays of light and prevent them from hastening the destructive oxidation of the linoxyn by the air.

11. Finer pigments afford more efficient protection than coarse pigments, since they are more thoroughly in contact with the oil.

12. Iron structures should be painted whilst their scale is still on after loosely adherent flakes and rust have been scraped off. The paint will last rather longer than if applied to the pickled or sand-blasted surface, and the labour of removing the scale is saved.

13. Experiments with rusty plates are not conclusive, but suggest that the rust need not be so carefully removed, prior to painting, as is usually thought to be necessary.

(*b*) Varnishing—the term 'varnish' is applied to such liquids as are produced by the solution of gums, resins, etc., in volatile substances such as spirit, turpentine, fusel oil, etc. Varnishes are open to the objection that they are not entirely impervious to gases and liquids. The application of several coats of varnish and the stoving of such articles as have been varnished tend to increase the efficiency of these types of protective. The former method of treatment is, of course, costly; the latter can only be employed where relatively small articles are being dealt with.

Frequently mineral oxides, etc., are added to give 'body' to varnishes, and such protectives are far preferable to the mere gum or resin solutions mentioned above. Provided the solvent utilised in manufacture is not too volatile and the substances employed to give 'body' to the varnish do not act injuriously upon either the iron or the solute, these varnishes are of considerable value. Of materials employed to give 'body' to varnishes, calcined hematite ores and the mixture of finely-divided zinc and zinc oxide ('blue powder') obtained in the distillation of zinc, are the most effective. (*Leeves.*)

(*c*) Coating with bituminous substances—the substances tar, pitch and asphalt, together with other tar products of like nature, form excellent protective coatings for iron and steel. Care requires to be taken to ensure the absence of acid or alkaline substances from these bituminous materials. Where the articles to be coated can be heated without deleterious effect most excellent 'enamels' can be produced by applying warm tar to the same as hot. A variety of coatings may be obtained by altering the relative temperatures of the articles to be treated and the bituminous material employed in treatment (*cf.* Angus Smith's process, page 2629).

(*d*) Coating with Portland cement—the use of cements as a protective coating is frequent where the same can be afforded suitable support. In many cases the difficulty of attachment of the protective coating more than counterbalances the rigidity and adherent properties of the cement. Consideration must, of course, be taken of the possible effect of metallic expansion and contraction upon the cement coating applied, and cement should only be utilised where it can be applied in relatively thick coatings and where one can be assured that rupture of the hardened cement will be unlikely.

(*e*) *Enamelling.*—The enamelling of iron and steel is frequently conducted with a view to afford protection to the same. The enamels employed are boro-silicates of sodium, potassium, calcium, and aluminium. Finely-divided glass, flint or quartz forms the general source of the silica; felspar or clay that of the alumina. To render enamels translucent fluorspar is added, while borax furnishes the anhydride of boron required to complete the true enamel. Soda ash and pearl ash are utilised as fluxes. As oxidising agents the nitrates of sodium and potassium and manganese dioxide are used in light- and dark-coloured enamels respectively. To give adhesiveness to such enamels as come into direct contact with the metals to be coated, oxide of cobalt is employed. The following oxides are used as colouring agents:—

White, oxide of tin; blue, oxide of cobalt; violet, oxide of manganese; brown, oxide of manganese; grey, oxide of nickel; green, oxides of copper or of chromium; yellow, oxides of uranium or of titanium; red, oxides of iron, selenium, or of gold.

The enamel is put on either as a powder or as a suspension. It may be applied in one coat either by dipping, by spraying, or by powdering. Sometimes, however, a non-vitreous base material is applied and burned in to make it adherent, after which the true enamel is introduced to the surface to be coated. In any case the finely-divided particles which form the basis of the enamel are fused together in a solid coating of boro-silicate by subjecting the same to a temperature of about 1,000°C. The process generally requires from 3 to 4 minutes.

A process similar in some respects to that of enamelling is Ward's inoxidising process, which consists of the application of a solution of a silicate to the iron or steel to be protected. The articles so prepared are heated to such a temperature as will cause partial fusion of the silicate to occur and union of the same with the iron finally to ensue (*cf.* also Dode's inoxidising process).

It is obvious from the above that enamelling can be applied to relatively few articles of importance to the engineer.

2. Compound Coatings.

The term 'compound' is applied here to such protective coatings as are produced by chemical action, the ultimate result of which is the formation of a chemical compound, such, for example, as magnetic oxide of iron (Fe_3O_4), iron-zinc ($FeZn_7$), etc. The compounds formed may be, as already noted, either chemical (in the general sense of the term) or intermetallic (in the specialised sense of the term).

Chemical Compounds.

Barff's process consists in passing superheated steam over the objects, which are heated in an air-tight retort to about 260° C.; for the formation of a more perfect protective coating higher temperatures are necessary (650° C.). Articles so treated are said to be 'barffed.' Relatively small objects only can be treated as above. The coating formed consists of the mixed oxides of iron (Fe_2O_3 and Fe_3O_4).

The Bower-Barff process is an improvement on the above, and consists in the heating of the objects to be protected to about 900° C., at the attainment of which temperature superheated steam is introduced to the same, which has the effect of producing a coating of the mixed oxide already referred to. This operation having continued for about twenty minutes, carbon monoxide is injected into the retort for a period of from fifteen to twenty-five minutes, during which time the entire reduction of the coating to the condition of magnetic oxide of iron is completed.

The Gesner process treats iron and steel at a moderately high temperature (550° C. to 650° C.) In a retort whereinto may be introduced an atmosphere of steam. The preliminary heating occupies twenty minutes; the steam is then allowed to react with the oxide formed in the first operation for about half an hour, when naphtha is introduced and allowed to remain in contact with the material under treatment for about ten minutes. Finally, steam is again introduced. The whole sequence of operations occupies about one hour and twenty minutes.

The Parker 'dry' process.—Under a patent assigned to the Parker Rust-proof Company, of Detroit, the formation of an adherent coating of oxide may be obtained by first heating the objects to be treated to about 600° F. and then subjecting them to fumes of the acid metaphosphates of strontium, molybdenum and tungsten.

The Hans Renold process.—Remove all grease or oil from the articles to be treated by suspending in a bath of hot lyco (11 oz. per gal.) for about three minutes, wash in cold running water for a few seconds, then suspend from cathode brass bars by steel hooks in an electrolytic bath (KCN, 98 per cent. pure, 4 oz. per gal. of water), iron plates forming the anodes. Leave here for five minutes, and when a current of 25 amps. at 8–10 volts is passed through the bath all foreign matter on the surface will be removed. Wash off the cyanide by means of hot water to facilitate drying.

Heat the articles to 700° C., then quench in cotton-seed oil by immersing in the main body of the quenching tank for seven or eight seconds before allowing to fall to the bottom.

Dry by heated sawdust and hot-air blast (dried and filtered by passing through calcium chloride and cotton wool).

Insufficient oxidation results in the finished bodies having a grey appearance, due to the atmosphere of the furnace containing too much gas. Blistering is due to overheating.

Villon's process consists in subjecting the iron or steel to be protected to the vapour of sulphur, as a result of which treatment the monosulphide of iron is found.

The Bertand process requires that the articles to be treated be thoroughly cleaned by sand-blasting or similar means before they are immersed in a bath, such as will lead to the deposition of copper upon the same as a result of reaction between the iron and a suitable electrolyte. The deposition may be achieved by the application of electricity or by more purely chemical means. After thorough washing the articles are heated in an oxidising atmosphere to a temperature of about 600° C., which treatment leads to the formation of a fairly adherent coating of magnetic oxide of iron.

The De Meietin's process depends upon the formation of a coating of magnetic oxide (Fe_3O_4) upon iron or steel which is placed as the positive pole in a bath of distilled water, maintained at a temperature of from 70° C. to 80° C., a current of electricity being passed through it. The oxide coating is adherent, provided the current density is not over great, and may be rubbed and polished. This method is of value in the treatment of such articles as cannot be submitted to any processes which might tend to temper or anneal the objects under treatment.

The Parker 'wet' process (patent) consists in the immersion of the iron or steel to be protected in a bath of a 1½ per cent. solution of the acid metaphosphates of tungsten, molybdenum, or any of the metals of the third, fourth or fifth group of elements.

The Coslett Process (Coslettising).—Cast iron or steel articlestreated by this process are not only rendered rust-proof but improved in appearance.

The articles to be treated should be perfectly clean and free from tin, nickel, or grease.

The best results are obtained on a frosted surface, such as is left by sand-blasting or pickling. Sand-blasting is to be preferred, as any traces of acid render the treatment ineffectual.

The coslettising bath is prepared by heating in a cast-iron or welded steel tank a sufficient quantity of distilled water to easily cover the articles to be treated. When boiling add for every gallon of water in the bath (1) two ounces of phosphoric acid (syrupy sp. gr. 1·5); (2) one ounce of iron filings. This should be carried out in the open or under an uptake, as the reaction results in the formation of disagreeable fumes. When this reaction has ceased the bath is ready for use.

The articles should be placed in the bath as soon as possible after sand-blasting, and should be gently boiled for two hours.

A second tank should be prepared containing distilled water, which should be heated in time to wash the articles as taken from the coslettising bath.

At the expiration of the specified time the articles should be taken from the coslettising bath and placed directly into the hot water and thoroughly scrubbed with a stiff bristle brush.

They may then be dried off, and if heavy will dry quickly themselves, but if light should be placed in an externally heated oven.

As soon as dry and while warm they should be dipped in a mixture of lubricating oil and turps substitute, in the proportion of 2 to 1, and left to drain. When cold, surplus oil may be removed with clean waste or wiper.

To allow for evaporation of bath a mixture similar to that in the bath should be made up and added as required.

To keep the bath at the correct strength it is necessary to titrate a sample of the bath with $\frac{1}{10}$ normal sodium hydrate. To make this test, 10 c.c. of the bath should be placed in a conical flask, a few drops of phenolphthalein solution being introduced as an indicator. The $\frac{1}{10}$ normal sodium hydrate should be added from a burette, until a permanent pink tinge is given to the liquid in the flask. The amount of sodium hydrate dropped into the flask should be noted, and if the bath is correct this amount will be 10 c.c. If more sodium hydrate is used, the bath is too strong and will require diluting with distilled water; if less is used, the bath is weak and will require the addition of phosphoric acid and iron filings in the given proportion.

The appearance of the deposit obtained on the article is a rough guide to the state of the bath. The proper deposit is of a uniform dull black colour, but if the bath is too strong this black coat is covered with a pearly white deposit which will not scrub off. If the bath is too weak the articles appear unevenly covered with a thin grey coat.

It is stated that in the present coslettising process (which cannot be used except under licence from the Coslett Anti-Rust Syndicate) phosphorised zinc, made under special conditions, is used instead of phosphorised iron, the solution otherwise being prepared in much the same manner. This newer process is said to give much better results, and the depth to which the articles are rust-proofed to be considerably greater.

The need for the absolute cleanliness of the articles before treatment cannot be too strongly emphasised, and they should not be handled after cleaning, or before they are finally oiled.

Intermetallic Compounds.

Sherardising.—The articles to be coated are first cleaned and dipped in an acid bath as for galvanising; they are then put in a suitable retort which is, if possible, airtight, and are surrounded with 'blue powder'; the retort is then raised to a temperature of 500° or 600° F.

If the retort cannot be made airtight, about 3 per cent. of finely powdered carbon should be mixed with the zinc to prevent the formation of zinc oxide.

The heat is kept up for a few hours, after which it is allowed to gradually decrease.

A coating is formed which consists mainly of an intermetallic compound of zinc and iron ($FeZn_2$).

Calorising.—A somewhat similar process to the above, in which aluminium powder is utilised as the agent and wherein the resultant protective coating consists chiefly of an intermetallic compound of iron and aluminium.

Rustless Iron.

The composition of rustless iron (carbon, 0·7; silicon, 0·8; manganese, 0·12; chrome, 11·7, and nickel, 0·57) is, except for a variation in the carbon content, the same as that of the steel possessing similar qualities.

Colouring Metals Electrolytically.

Chiefly in grey, so as to give the effect of old metal, is largely carried out.

When the colouring is only to be partial, a shellac or asphalt varnish is applied to the parts it is desired to leave untouched. The *Ironmonger* points out that with cyanide baths the retention of the varnish on the metal is almost impossible, and that in all such cases it is desirable to use a bath of acid reaction.

For a grey surface on iron a bath of the following composition is recommended:—

12 litres water.		100 grammes white arsenic.	
4	„ crude hydrochloric.	100	„ green vitriol.

1 litre of ferrous chloride solution.

As usual with acid baths, a considerable strength of current is required. Plates of carbon are used as anodes.

The bath can be used for colouring silver, nickel, German silver, etc., and by altering the composition of the bath and the current from grey to a deep black is produced; but the black adheres very indifferently—a high current is necessary for the latter. (*Horobin.*)

Electro-Deposition of Iron.

A bath that will give very satisfactory results is composed of 75 grms. of ferrous ammonium sulphate to 1 litre of water, with a current density of 1 amp. per 30 sq. cms. To ensure a uniform deposit the anode should be moved about the work by means of a small motor. A good anode is made up of 16 S.W.G. Swedish iron wire wound into the form of a cylinder and thoroughly annealed. The temperature of the solution should be kept above 68° F., and it is desirable to decant and settle it every three days or so to remove oxides of foreign matter which cause roughness in the deposited metal.

It has been found possible to coat with a layer 2 mm. thick any cylindrical wrought iron or steel surface. Properly done this layer cannot be chipped off with a chisel, and when carboulsed and hardened the dividing line, shown by microphotographs, entirely disappears. The surface can be filed or ground and given a high finish.

(B. H. Thomas, 'Institution of Automobile Engineers.')

COPPER.

Copper containing at least 99·95 per cent. of the pure element is produced on a commercial scale in large quantities. The average tenacity of cast copper is about 10 tons per square inch, that of worked copper is about 15 tons per square inch, while Roberts-Austen quotes the following figures for the mechanical properties of slowly annealed, hammered, rolled bars of copper of a high degree of purity :—

Elastic limit	1·16 tons per sq. in.
Maximum stress	13·47 ,,
Elongation	37·0 per cent.
Reduction of area	61·0 ,,

Impurities in Commercial Copper.

Arsenic.

Arsenic increases the hardness and the tenacity of copper. When present in moderate quantities it increases the percentage elongation of the metal. It improves the rigidity and strength of copper at high temperatures, hence, for fire-box plates, the use of copper containing from 0·3 per cent. to 0·5 per cent. of arsenic is frequently specified. In copper that is to be employed in the manufacture of brass subsequently to be cold-worked, not more than 0·05 per cent. of arsenic should be allowed.

Antimony.

Antimony is similar in action to arsenic, but it should be limited to traces in such copper as is to be used for the manufacture of brass that is to be cold-worked.

Bismuth.

Bismuth being the most deleterious element that can be present in copper, owing to its tendency to induce red-shortness, not more than traces of this element should be allowed.

Iron.

Iron is rarely present in copper in more than traces.

Lead.

Lead is, after bismuth, the most objectionable impurity likely to be present in copper, although it is of value in metal that is to be rolled into sheets, on account of its softening effect on copper. Not more than the smallest quantities of this element should be allowed in copper for cold-worked brass.

Nickel.

Nickel hardens copper, but is in no way deleterious when present in such amounts as are usual in commercial copper.

Oxygen.

Oxygen in small quantity does not have any very radical effect on the mechanical properties of copper. It is important in bringing copper up to the 'pitch,' and in combining with deleterious impurities to form insoluble and infusible compounds, thus separating and distributing these impurities and rendering them harmless.

Sulphur.

Sulphur tends to embrittle copper, but is rarely present in refined copper.

Tellurium.

Tellurium is similar to sulphur in its action on copper.

Silver, Tin, and Zinc.

Silver, tin, and zinc are sometimes present in copper, but are rarely present in such quantity as to have much effect on the metal.

It has been found practically impossible to cast copper which is mechanically sound and of high electrical conductivity, on account of the porous metal that is obtained. By an addition of boron this can be accomplished. One per cent. of boron suboxide flux—equivalent to 0·08 to 0·1 per cent. of boron suboxide—is added to the copper, and a casting that is commercially sound is obtained.

ZINC.

Zinc is marketed in two forms—as sheet zinc (see Sheet Zinc Trade Gauge, page 2663) and as spelter, i.e. flat rectangular ingots from 1 to 2 inches in thickness. The tenacity of zinc as cast is about 1 ton per square inch, and its elongation is practically nil. Zinc, after compression under a stress of 20 tons per square inch at 100° C., has a tenacity of about 11 tons per square inch.

It is ductile between 212° F. and 302° F. and can then be shaped as required. But when either above or below these limits it becomes brittle and unpliant, and therefore not adapted for treatment. It melts at about 786° F. if volatilisation is guarded against.

Impurities in Commercial Zinc.

Arsenic.

Arsenic is a common impurity in spelter. It does not occur in such quantity as to have a deleterious effect upon the mechanical properties of spelter or of such alloys as contain it. It is, however, an objectionable ingredient in such zinc as is to be employed in the production of hydrogen.

Cadmium.

Cadmium is nearly always present in zinc; in electrolytic varieties of the metal it rarely exceeds 0·07 per cent., in other varieties as much as 0·40 per cent. is found. The effect of this element is to harden spelter and to make it more brittle. Cadmium is, on this account, objectionable when the zinc has to be rolled into sheet or to be used for galvanising telegraph wires. In zinc for the manufacture of brass subsequently to be cold-worked as much as 0·20 per cent. of cadmium may safely be allowed.

Copper.

Copper tends to harden zinc, but is rarely present in quantity sufficient to effect radical change in the metal.

Iron.

Iron hardens and embrittles zinc. Its presence tends to the formation of dross in the galvanising process.

Such zinc as is to be used in the manufacture of cold-worked brass should not contain above 0·10 per cent. of iron. Electrolytic spelters rarely contain above 0·025 per cent.; as much as 2·5 per cent. of iron is, however, to be found in certain zincs.

Lead.

Lead is present in certain brands of zinc up to 2·5 per cent. The purer brands of spelter contain up to 0·20 per cent. of lead. The presence of lead is not deleterious where the spelter containing it is to be used for general brass manufacture, but where brass is to be cold-worked or specially treated care must be taken that the spelter used has not too high a content of lead.

Lead in moderate quantity tends to make zinc softer in rolling. When present in quantities in excess of 0·7 per cent. it tends to the production of serious cracks in slush castings of zinc.

Other elements occasionally present in spelter in traces are sulphur and carbon.

TIN.

The London Metal Exchange form of contract (1911) for the purchase of tin recognises two classes of tin—Class A, tin assaying not less than 99·75 per cent. of pure metal; Class B, tin assaying not less than 99 per cent. of pure metal.

The tensile strength of cast tin varies (according to Thurston) from 2,000 to 6,000 lbs. per square inch. The elongation is, for all practical purposes, nil.

The principal impurities in commercial tin are lead, iron, copper, and arsenic. Sulphur, silver, bismuth, and antimony are of frequent occurrence.

NICKEL.

Nickel containing small quantities only of impurities is a commercial article. On account of its readiness to occlude carbon monoxide and other gases, and its affinity for carbon, it is difficult to

obtain nickel in a pure state in the cast condition. Parker, experimenting on pure, dead soft, wrought nickel, has arrived at the following figures for the mechanical properties of nickel :—

Elastic limit	6–10 tons per sq. in.
Maximum stress	18–20 ,,
Elongation	8–15 per cent.

Impurities in Commercial Nickel.

Carbon.

Carbon is present in nickel up to 0·20 per cent., though it rarely exceeds 0·15 per cent. It has an embrittling effect on nickel when in the form of graphite, but when combined with nickel as nickel carbide it has a strengthening effect.

Cobalt.

Cobalt has a strengthening and hardening effect on nickel, but in the quantities—up to 1·00 per cent.—usually found in commercial nickel, this element has but little effect.

Copper.

Copper is similar to cobalt in its action, but rarely exceeds 0·20 per cent. in amount.

Arsenic.

Arsenic should not exceed about 0·025 per cent. in such nickel as is to be subjected to cold-work, or in alloys for a similar purpose.

Iron.

Iron has an effect on nickel similar to that of cobalt and chromium, but, being rarely present in quantities in excess of 0·75 per cent., its presence is scarcely noticeable.

Silicon.

As much as 0·30 per cent. of siliceous matter can be present in commercial nickel. Its effect on the properties of the nickel is uncertain.

Sulphur.

Sulphur is occasionally noted in samples of nickel.

Nickel, if it is to be satisfactory for the manufacture of copper-nickel alloys for cold-working, should be free from all unreduced oxides.

CHROMIUM.

The colour of chromium is silver-white. Nickel has a little more of a yellow tinge to it than chromium. On the other hand, chromium will hold its colour indefinitely. Nickel will turn almost black in a laboratory atmosphere, and chromium will stay bright indefinitely. It is about the only metal known that will stay bright in a laboratory atmosphere. Not even platinum will stay as bright. See also p. 2542.

ALUMINIUM.

Aluminium which contains up to 99·9 per cent. of the pure element can be produced on a commercial scale, but the commercial metal is rarely above 99·5 per cent. pure. The mechanical properties of cast aluminium are as follows :—

Elastic limit	3–4 tons per sq. in.
Maximum stress	5–7 ,,
Elongation	3–4 per cent.

The tenacity of hard-rolled aluminium can be as high as 18 tons per square inch.

Annealing Sheet Aluminium.

1. Prepare a mixture of ordinary whiting and oil, mixed to the consistency of thick paste. Coat the metal on both sides with this preparation, and place it on a clean fire or in a furnace, allowing it to remain until the oil in the paste becomes ignited. When this occurs withdraw the work from the furnace and allow it to cool gradually. The coat of whiting should then be removed from the surface of the metal by washing and brushing.

2. Heat the metal to a dull red colour, perceptible in the dark, and cool slowly. With this method care must be exercised to get an equal annealing temperature distributed over the entire surface of the work.

3. Heat the sheet aluminium until pine-wood sawdust just glows when sprinkled on it, which indicates a temperature of about 750° F. At this temperature a dry match-stick will just char when rubbed on the metal. (*A. Eyles*, '*Machinery*,' *Aug.* 11, 1921.)

The Protection of Aluminium from Corrosion.

Aluminium and its alloys can be efficiently protected against atmospheric corrosion under the most severe conditions only by the use of an enamel or varnish paint. Oil paints are very inferior in protective power to those referred to above.

Impurities in Commercial Aluminium.

Copper.

Copper is present in aluminium in quantities up to 0·10 per cent., which quantities are insufficient to affect the properties of the metal noticeably.

Iron.

Iron has the effect of hardening aluminium, but is never present in sufficient amount to cause appreciable change in the physical properties of the metal. The iron content varies generally from 0·25 to 0·75 per cent.

Silicon.

Silicon is always present in aluminium, varying in percentage from 0·25 to 0·50 per cent. Occasionally the upper limit given is exceeded; excessive quantities of silicon render aluminium susceptible to atmospheric corrosion.

Sodium.

Sodium is now occasionally, though rarely, noted in aluminium.

Copper, Nickel, Zinc, and Magnesium.

Copper, zinc, nickel, and magnesium harden aluminium and are frequently employed for the purpose in question. They are rarely, with the exception of copper, present in commercial aluminium.

MAGNESIUM.

Magnesium, which is a lighter metal than aluminium, promises to play an important part in the future of light alloys, particularly for aircraft construction.

NON-FERROUS ALLOYS.

COPPER AND ZINC.

The alloys of copper and zinc containing over 50 per cent. of copper are generally termed 'brasses.' The mechanical properties of these alloys have been the subject of numerous investigations; in this connection such authorities as Thurston, Charpy, Lohr, Guillet, etc., should be consulted.

Below are given the results of Guillet's tests on the brasses. His tests were carried out upon material which was worked, then heated for ten minutes at 750°C. in a salt bath and finally cooled in air.

Alloy Composition.	Yield Point.	Max. Stress.	Elongation per cent. on 100 mm.	Hardness.

Figs. 34 and 35 show the relation existing between the mechanical properties of the pure brasses and their copper content.

The casting temperatures of these alloys are of exceptional moment. The following tests show the influence of varying casting temperature on the tensile properties of 40·5 per cent. zinc-copper alloy castings poured from one crucible within a short interval of each other. Chemically the three castings were identical.

Casting Temperature °C.	Maximum Stress per Square Inch.	Elongation per cent.
1,038	12·45	6·0
943	16·28	9·5
934	18·88	15·0

FIG. 35

In every case with other alloys similar temperature variations have a similar effect on the mechanical properties. The following results obtained from manganese bronze were obtained by Guillemin :—

Casting Temperature °C.	Maximum Stress. Tons per Sq. In.	Elongation per cent.
1,400	15·2	13
1,300	19·7	45
1,250	21·6	35
1,200	22 0	30

In judging a suitable pouring temperature the appearance of the alloy in ladle or crucible may be used as a guide. With manganese bronzes this appearance is somewhat confused by the aluminium present, for, as is well known, this imparts a characteristic skin to the surface of the molten alloy. The practical effect of this is to make the alloy appear colder and less fluid than is really the case. Careful observation readily overcomes this difficulty.

There is little doubt that the pyrometer is, in the hands of careful workers, the best means of determining the temperatures of metal or alloy in the ladle or crucible.

(See also Zinc-Tin Alloys, page 2572.)

Cast Brass.

Cast brass is somewhat variable in composition, but usually contains about 66 per cent. of copper, this percentage being that found in English standard brass.

The metals employed in the production of cast brass are not generally selected with such care as are those used in the manufacture of malleable brass. Lead, tin and iron are common impurities.

Lead in proportions varying from 1 to 3 per cent. is frequently added for the purpose of facilitating machining. It reduces the tenacity and hardness and increases the corrodibility of the resulting alloy, and is liable to segregate in those parts of the castings that solidify latest on cooling.

Tin tends to harden brass and is added in quantities up to 3 per cent., though 2 per cent. is not generally exceeded.

Iron hardens and increases the tenacity of brass.

The presence of more than one of these elements in quantity is to be deprecated, as their combined effects on the mechanical properties of the resulting alloy are likely to be injurious.

The mechanical properties of cast brass of average composition (66 per cent. of copper) and containing only small quantities of impurities or added elements are :—

Yield point, 6 tons per sq. in. ; Tenacity, 14 tons per sq. in. ; Elongation, 40 per cent.

A number of alloys, adapted for particular purposes, are tabulated below :—

Alloy.	Cu. Per cent.	Zn. Per cent.	Other Metals. Per cent.
Very delicate castings	86·00	14·00	—
Good yellow brass	75·00	25·00	Sn. 2·00
Name plates	86·00	9·00	Sn. 3·00 ; Pb. 2·00
Small castings (red)	90·00	10·00	,, ,,
Taps, cocks, etc.	78·00	14·00	Sn. 3·00 ; Pb. 3·00
Fine castings (yellow)	71·00	24·00	Sn. 2·00 ; Pb. 3·00
Hydraulic pumps	58·00	38·00	Sn. 2·00 ; Fe. 2·00

Ductile Brass.

The brasses containing upwards of 63 per cent. of copper are ductile and malleable at ordinary temperatures, provided that the metals used in the production of the alloys be of the best quality, and that the alloys be well annealed during working. The most suitable annealing temperatures for ductile brass are between 650° C. and 700° C.

Lead is admissible in alloys that are to be rolled into sheet, but is injurious in alloys that are to be drawn into wire. It should not be present in such quantity as is liable to create trouble at the annealing furnace.

The most ductile of the brasses contains 70 per cent. of copper and possesses the following mechanical properties when fully annealed subsequent to rolling :—

Yield point . 10 tons per sq. in. ; Elongation . 60 per cent. on 2 ins. ;
Maximum stress . 23 ,, ; Hardness (Brinell) 120.

Hot-forgeable Brass.

The alloys of copper and zinc containing from 59 to 61 per cent. of copper are characterised by their ability to withstand hot rolling at temperatures ranging from 500° C. to 800° C. They are employed in sheet form for the sheathing of wooden ships and in bar form for the manufacture of bolts, fastenings, etc. They are forgeable under the drop hammer and, hence, are frequently used in the manufacture of stampings. In this last connection it is particularly noteworthy that constancy of composition must be attained, on account of the large variations in machining properties accounted for by small changes in the copper content. The alloys in the range 57 to 63 per cent. of copper are forgeable, though not capable of withstanding rolling, in the temperature range already stated, and may be considered here.

All the above alloys are retained in a harder, stronger, and less ductile condition if quenched from temperatures between 750° C. and 800° C. than if allowed to cool slowly. They are liable to spontaneous cracking if worked at temperatures below 600° C., which liability, if thought to be inherent, can be lessened if the alloys are annealed at temperatures between 200° C. and 300° C., subsequent to working. The best temperatures for annealing, with a view to reducing variations in the mechanical properties due to variations in the mechanical and thermal treatment, are below rather than above 650° C. The temperature range (750° C.–800° C.) is, according to Stead, a dangerous one in which to conduct the annealing of hot-forgeable brass.

The average mechanical properties of fully annealed cast 60/40 brass are as follows :—

Yield point . .	. 10 tons per sq. in.;	Elongation . .	. 35 per cent.;
Maximum stress	. 25 ,, ;	Hardness (Brinell)	. 85.

Drawn rod of 60/40 composition is obtainable having the following average mechanical properties :—

Yield point	. 28 tons per sq. in.;	Elongation . .	20–30 per cent. on 2 ins.;
Maximum stress .	32 ,, ;	Hardness (Brinell)	140.

The last factor appears to be dependent on the diameter of the rod in question, being least when the diameter of the rod is greatest. On account of the almost infinite variety of hot- and cold-working possible in the treatment of these alloys almost infinite variations in mechanical properties are obtainable.

Effect of certain Metals on Brass.

TIN.

Naval Brass.

Tin raises the tenacity, increases the hardness and resistance to corrosion and lessens the elongation of the 60/40 alloy, to which it is added commercially to make Naval brass. The latter contains 60–62 per cent. copper, 1–1½ per cent. tin, and the rest zinc. Not more than 2 per cent. of tin should ever be present ; 4 per cent. induces great brittleness.

IRON.

Iron increases the tenacity and hardness of brass. The difficulty of dissolving iron in brass was first overcome by a special process, the invention of Dick (see also p. 2560), whose alloy, generally containing 55–57 per cent. copper, 42 per cent. zinc, 1–2 per cent. of iron and traces of phosphorus, is well known.

Iron is now generally added to brass in the form of ferromanganese, an alloy of iron and manganese which is readily dissolved in molten brass.

MANGANESE.

Manganese 'Bronze.'

Manganese is added to brass with a view to improve the mechanical properties of the same. The resulting alloys are divisible into two classes.

(*a*) Alloys in which either no manganese or traces only of manganese are present, i.e. alloys to which the element has been added for purposes of deoxidation.

(*b*) Alloys in which appreciable quantities of manganese are retained in solution. These may be subdivided into (i) such as are suitable for rolling into rod and containing up to 0·05 per cent. of manganese, and (ii) such as are suitable for casting and containing less than 60 per cent. of copper, and up to 2·0 per cent. of manganese.

The manganese is introduced into the alloys by the addition of ferromanganese or cupro-manganese.

These alloys are forgeable when heated to temperatures above 750° C. They resist the corrosive action of sea water, and are employed in the manufacture of ships' propellers. Iron, aluminium and tin are generally present in manganese 'bronze.'

The analyses of the alloys known under this name are varied in accordance with the character and nature of the purpose for which they are combined, and as the results depend entirely upon

Parsons No. 1 alloy	32	16	15 ,, 25

CROTORITE BRONZE.

This new alloy, one of The Manganese Bronze & Brass Co.'s specialities, is zinc free, of steel-like qualities, and particularly recommended for bars and forgings subject to corrosion and high temperature.

Tests—500° to 600° F.—18–20 tons elastic limit, 30–32 tons maximum stress, 20–30 per cent. elongation; with no loss of physical properties after prolonged heating; and at 800°F. the elastic limit is 17 tons □".

As a casting alloy the physical tests are more than double cast gun-metal.

DELTA BRAND ALLOYS.

The metals and alloys sold by the Delta Metal Co., Ltd. (of London and Birmingham), under their registered trade-mark 'Delta,' are employed for a very great variety of purposes, the composition varying widely according to the requirements and purposes for which each of these metals or alloys is more particularly adapted. Some of them are based upon the introduction and chemical combination of definite quantities of iron and other elements in copper-zinc alloys. The effect of iron on brass has already been noted; the difficulty of introducing it in definite quantities was first overcome by the late Mr. Alexander Dick, the founder of the Delta Metal Co., Ltd., who adopted the name 'Delta' (the Greek equivalent of the initial letter of his name) as a trade-mark. In most of the alloys which may be classed under the 'Brasses,' the copper content lies between 57 and 62 per cent., that of zinc between 42 and 38 per cent., whilst some contain iron, phosphorus, manganese, or other metals, up to a total of about 2 per cent.

The following alloys, designated by the trade name 'Delta,' and manufactured by the Delta Metal Co. Ltd., find wide application.

Delta Bronze Nos. I and IV are practically incorrodible, and consequently of very great durability, even when used in strongly corrosive mine-waters, etc.; they are not attacked by sea-water, and resist acids much better than other copper alloys. On account of their great strength and resistance to corrosion, these alloys are largely used for parts of marine engines and mining and hydraulic plant which require a strength not less than that of the best steel, but at the same time freedom from corrosion—such as pump rods, piston rods, shafts, cranks, plungers. spindles, rams, etc. For propellers and propeller blades, Delta bronze is in great demand, and it is also successfully used for parts of ordnance, etc.

These alloys are malleable bronzes of very great strength, exceeding, even in the cast state, the strength of mild steel. They can be cast with facility, and will produce perfectly sound and homogeneous castings. When heated to a dull red heat, they become soft and highly malleable, and can then be readily forged, stamped, rolled, or pressed, to any extent required. These operations increase the strength considerably, as will be seen by the following copies of tests.

Description of Metal.	Diameter. In.	Area. Sq. in.	Ultimate Strength. Tons per sq. in.	Elongation in 2 ins. Per cent.	Reduction of Area. Per cent.
		Delta Bronze, No. I.			
Cast	0·500	0·1963	41·30	20·0	20·4
Extruded bars	0·502	0·1979	49·82	26·0	24·9
		Delta Bronze, No. IV.			
Cast	0·611	0·293	23·89	21·0	20·1
Extruded bar	0·500	0·1963	37·1	27·0	20·0

Extrusion Process.

The process of extruding copper and its alloys, the invention of the late Mr. Alexander Dick, developed and worked by the Delta Metal Co., Ltd., of London and Birmingham, under numerous subsequent new patents and improvements, consists of the pressing or squeezing of heated metals through dies of any desired cross section, by hydraulic pressure varying according to the section to be produced and the character of the metal operated upon.

Dick's extruded bars have a perfectly smooth and uniform surface, free from cracks or other defects; size and shape are of the greatest accuracy, and owing to their superior finish, machining is reduced to a minimum. The Company are able to produce extruded rods as ordinary round or pinion wire weighing a fraction of a pound per foot per run, to heavy round, square or hexagon rods, or other sections, more or less complicated, weighing as much as half a cwt. and over per foot. The facility of manipulation ensures rapid output, so that sections not regularly kept in stock can be supplied at very short notice.

The Delta Metal Co., Ltd., are not only the original, but claim to be also the largest manufacturers of extruded rods and sections. They supply these in various metals and alloys: in 'Delta' bronzes Nos. I, II, IV, and VII, Heagard bronze, manganese and aluminium bronze, brass, yellow metal, naval brass, etc.

They make a speciality of high-speed turning and screwing brass ('Delta' Brand and 'Dixtrudo' Brand) in every variety of shapes and sections. This material, like the stampings and pressings in brass, bronze, and copper made by the Delta Metal Co., Ltd., is used largely for repetition work and mass production, and supersedes castings.

Bull's Metals.

Bull's Metals are strong, malleable alloys of good casting qualities, and equal to good gunmetal in resistance to corrosion. They are manufactured in two qualities, No. II and No. III.

Alloy No. II is suitable for founding purposes, and extensively used for propellers and propeller blades, parts of guns and gun carriages, requiring the strength of cast steel with great toughness and resistance to corrosion.

Alloy No. III is very malleable and can be rolled, forged, stamped, or otherwise wrought at a red heat; this metal also casts well. Its composition ensures great resistance to corrosion and wear. It is absolutely non-magnetic.

Rolled in round, hexagon, angle, and section bars, or into sheets and plates; forged or stamped Bull's metal is used for pump rods, centrifugal pump spindles, rams, stern shafts, sluice valve spindles, parts of marine and hydraulic machinery generally. Forged propeller blades, propeller studs and nuts. Bolts, nuts, screws, studs, and nails. Parts of torpedoes and torpedo boats, ordnance, ammunition, etc. Condenser plates, strainer plates, doctor blades. Hull plates and angles for launches, torpedo boats, yachts, sailing and rowing boats.

The elastic and ultimate resistance to tensile, crushing, and torsional stresses are greater in the case of wrought Bull's metal than in mild steel, and higher working strains may therefore be used with Bull's metal. Where resistance to the action of water or chemicals enters as an important factor, Bull's metal, whether wrought or cast, becomes specially superior to steel.

Tensile Tests of Bull's Metals.

Dimensions.	Area. square inch.	Reduction area at fracture.	Extension.	Ultimate Stress.	Remarks.

NICKEL.

Nickel Silver.

The alloys of copper, nickel and zinc containing from 45 per cent. to 65 per cent. of copper, 5 per cent. to 30 per cent. of nickel and 15 per cent. to 25 per cent. of zinc are of commercial importance and are classified under the general title of 'nickel silver.' The metals employed in the manufacture of these alloys must, if the same are to be used in the production of cold-worked articles, be of the highest degree of purity. For the manufacture of castings, metals of a lesser purity may be used.

Lead, tin, iron and unreduced oxides are the impurities generally present in nickel silver. Lead is occasionally added to nickel silver in quantities up to 3 per cent. when the same is to

be employed for casting. Tin in quantities upwards of 2 per cent. has a hardening and embrittling effect on the alloy, while iron in similar quantity has a hardening effect only. The addition of any of these elements results in injury rather than benefit to the alloys and especially increases the corrodibility of the same.

The effect on the mechanical properties of nickel silver of almost constant copper content of increasing the nickel content has been admirably shown by Thompson (Institute of Metals, March 1916), from whose paper on 'The Annealing of Nickel Silver' the following table is taken :—

TENSILE TESTS ON CAST BARS.

Cu.	Zn.	Ni.	Mn. added.	Yield Pt. Tons per sq. in.	Maximum Stress. Tons per sq. in.	Elongation. Per cent. on 2 ins.	Reduction of area. Per cent.
60·6	31·7	7·6	—	7·16	16·88	34·5	37·2
60·2	31·8	7·8	0·25	6·60	15·28	46·5	46·9
61·8	21·7	16·4	—	9·00	17·80	39·5	32·7
61·2	23·2	15·5	0·25	8·12	18·36	39·0	45·9
61·6	15·9	22·4	—	8·52	17·20	24·5	26·7
61·6	18·5	19·8	0·25	8·24	19·36	32·5	33·5
55·7	26·7	17·4	—	9·04	17·12	33·5	37·8
54·3	29·7	15·8	0·25	8·92	16·88	38·5	40·0
56·2	27·6	16·3	1·50	9·04	17·96	44·0	41·1
61·2	9·8	28·6	—	8·76	19·72	32·0	36·7
60·4	11·4	27·9	0·25	10·32	23·68	29·0	29·7
60·9	13·2	26·7	1·50	10·88	24·16	35·0	33·1

Other results of his research show that the tendency of commercial nickel silver to 'burn' is increased (*a*) by increasing the nickel content, (*b*) as the ratio of the zinc to the copper is increased, and (*c*) with the amount of impurities present.

The following alloy is stated to be possessed of the best all-round properties :—

Copper, 46 per cent. ; Nickel, 39 per cent. ; Zinc, 20 per cent.

Monel Metal.

This is a nickel alloy which resists corrosion and has a high tensile strength. It has an average composition of 67 per cent. nickel, 28 per cent. copper, and 5 per cent. iron, manganese, etc. It has a melting point of 1,360° C. (2,480° F.) ; specific gravity, 8·87 ; weight per cu. in. (cast), 0·319 lb. ; coefficient of expansion (20°–100° C.) ; ·00001375 per 1° C. ; heat conductivity $\frac{1}{15}$ that of copper ; shrinkage, $\frac{1}{4}$ in. per foot ; hardness (cast), 20–23 (Shore scleroscope) ; modulus of elasticity, 22,000,000–23,000,000 ; yield point (cast metal), 37,090 lbs. per sq. in. ; tensile strength (do.), 72,281 lbs. per sq. in. ; elongation (do.), 34 per cent. ; reduction in area (do.), 32 per cent.

Platnam.

Consists of 54 per cent. nickel, 33 per cent. copper, and 13 per cent. tin. It is used for the manufacture of valve seats and valves which have to withstand the action of superheated steam.

Platinoid.

Platinoid, introduced by Mr. F. W. Martin, is a kind of German-silver, with an addition of 1 to 2 per cent. of tungsten. The latter, in the form of phosphor-tungsten, is first melted together with a certain quantity of copper. In order to remove the phosphorus and a part of the tungsten, both of which separate dross, the resulting compound is several times remelted. Finally an alloy of a beautiful white colour is obtained, which when polished closely resembles silver, and retains its lustre for a long time. Platinoid has the properties of German-silver in a pre-eminent degree. It shows great electrical resistance, which remains almost constant at different temperatures, and is about 1½ greater than that of German-silver.

ALUMINIUM.

Aluminium Brass.

Aluminium acts as a deoxidiser and is added to cast and hot-forgeable brass, for the purpose of improving their mechanical properties, in quantities varying from 0·3 to 1·5 per cent.

Typical tests of cast aluminium brass, containing 38 per cent. of zinc, 2 per cent. of aluminium, and 2 per cent. of lead, are :—

Yield point	18 tons per sq. in.
Maximum stress	34 ,,
Elongation	12 per cent.

Melting Points of Commercial Brasses.

(*Gillett & Norton.*)

	Copper.	Zinc. (as desired).	Tin.	Lead.	Copper.	Zinc. (by analysis).	Tin.	Lead.	No. of Tests.	Melting Point.

Manganese brass	Copper 56, Zinc 41, Iron 1·5, Tin 0·9 per cent. Aluminium 0·45, Manganese 0·15 per cent.								6	870°C.

COPPER AND TIN.

Gun-metal.

The alloys of copper and tin containing upwards of 86 per cent. of copper are possessed of high tenacity and elasticity. Those containing from 89 to 91 per cent. of copper are the most important and are known as 'gun-metals.'

The addition of tin to these bronzes results in an increase in the hardness of the resulting alloy. Gun-metal is rarely manufactured from specially selected metals and frequently contains lead, zinc, etc. The Admiralty specification for gun-metal is as follows:

Copper	88 per cent.
Tin	10 ,,
Zinc	2 ,,

the specified tests for this material being

Maximum stress	14 tons per sq. in.
Elongation	7½ per cent.

Gun-metal containing 90 per cent. of copper and 10 per cent. of tin should give the following tests:—

Yield point	7 tons per sq. in.
Maximum stress	15 ,,
Elongation	15 per cent. on 2 ins.

Bell-metal.

The alloys of copper and tin containing from 75 to 86 per cent. of copper are used in the manufacture of bells; iron, zinc and lead are frequently added to the alloys either for cheapness or variety of tone.

Effect of Certain Elements on Bronze.

ZINC.

Gun-metal, Bearing Metal, etc.

The alloys of copper, tin and zinc are rarely, if ever, free from elements such as lead, iron, etc. These alloys may be divided into two classes:—

(i) Alloys containing from 7 to 12 per cent. of tin, up to 6 per cent. of zinc, and up to 2·5 per cent. of lead. These alloys, among which may be noted gun-metal to the Admiralty specification, are used in the manufacture of castings, such as cocks, stuffing-boxes and pump barrels, and for bearings which are subject to but little friction.

(ii) Alloys containing from 12 to 20 per cent. of tin, up to 5 per cent., though rarely more than 2·5 per cent., of zinc and up to 5 per cent. of lead. These alloys are used in the manufacture of heavy bearings, e.g. railway wagon and locomotive axle boxes. The majority of alloys of this class contain from 14 to 16 per cent. of tin and from 1·5 to 2·5 per cent. of zinc.

Zinc combines with the oxides and free oxygen of the bronzes, producing greater fluidity in the molten state, and hence freedom from 'pinholes' in the solid state.

LEAD.

Bearing Metal, etc.

The best bronzes should contain not more than 0·15 per cent. of lead, on account of its deleterious effect on the mechanical properties of these alloys generally.

Bearing metals having a bronze matrix and containing up to 40 per cent. of lead are in common use. A usual composition for bearings of this type is:—

Copper	64 per cent.
Lead	30 ,,
Tin	5 ,,
Nickel	1 ,,

The nickel is added to prevent the liquation of the lead. It increases the rate of cooling of the alloy and thus assists in the retention of the lead in the finely divided form.

Lead does not alloy with bronze, but separates out of the molten mass, as the same cools, in the form of globules. The lead bronzes may, therefore, be considered to consist of a network of bronze whose meshes enclose the lead content of the alloys in question.

PHOSPHORUS.

Phosphor Bronze.

Phosphorus acts as a deoxidiser and is added in small quantities for the purpose of deoxidation to copper. Not more than 0·15 per cent. is allowable.

The term 'phosphor bronze' is applied to the alloys grouped below.

(i) Bronzes to which phosphorus has been added as a deoxidiser and containing either no phosphorus or merely traces of the element.

(ii) Bronzes containing less than 9 per cent. of tin and up to 0·25 per cent. of phosphorus. These alloys are forgeable and are relatively non-corrodible. They are employed for rolling and drawing into wire and rod, and in the manufacture of general castings; in the latter case lead is occasionally added in quantities up to 5 per cent. The forgeable alloys of this group generally contain less than 5 per cent. of tin.

(iii) Bronzes containing from 8 to 14 per cent. of tin and from 0·25 per cent. to 1·00 per cent. of phosphorus. These alloys are employed for casting purposes in the manufacture of machine parts likely to be exposed to great friction. Lead up to 5 per cent. is added in certain cases.

Phosphorus is added to these alloys in the form of phosphor copper or phosphor tin.

The tensile strength of phosphor bronze varies from 14 to 18 tons per square inch, and the elongation from 6 to 10 per cent.

'DELTA' BRAND ALLOYS.

(The Delta Metal Co. Ltd.)

Delta Bronze No. V is an improved bearing metal of great strength and durability, and comparatively low price. It is particularly suitable for reducing friction at heavy pressures and high speeds, and is used for worm wheels for large cranes and other heavy machinery, hot neck rolls, locomotive slide valves, axle box, coupling, and connecting rod bushes, railway and carriage bearings, bushes, sliding surfaces, and other parts of machinery subject to heavy frictional wear. The metal is easy to tool, and requires no special precautions in casting.

Another metal used in lieu of phosphor bronze or gun-metal is 'Delta' Bronze No. VI, which produces fine, close-grained castings of great strength.

Melting Points of Commercial Bronzes.

(Gillett & Norton.)

	Copper.	Tin. (as desired).	Lead.	Zinc.	Copper.	Tin. (by analysis).	Lead.	Zinc.	No. of Tests.	Melting Point.
Gun-metal	88	10	—	2	—	—	—	—	4	995°C.

Leaded bronze	80	10	10	—	—	—	—	—	3	945°C.
Bronze with zinc	85	10	—	5	84·6	10·4	—	5·0	4	980°C.

COPPER AND ALUMINIUM.

Aluminium Bronze.

The alloys known as the 'aluminium bronzes' are solid solutions of copper and aluminium containing not less than 88 per cent. of copper. Of these alloys that containing 10 per cent. of aluminium is the strongest, though the alloys containing less than this percentage are of industrial importance. These 'bronzes' are of use, firstly, on account of their valuable mechanical properties and, secondly, on account of their resistance to corrosion. They are malleable both when hot and when cold; the alloys containing between 8 and 12 per cent. of aluminium are affected in a marked degree by heat-treatment.

Following are tabulated the mechanical properties of some of these alloys:—

Percentage of Aluminium.	Yield Point. Tons sq. in.	Max. Stress. Tons sq. in.	Elongation. Per cent. on 4 in.	Remarks.
2·5	—	20·0	40·	Cast.
5·0		25·0	55·	Cast.
10·0	18·0	35·0	25·	Cast in chill.
10·0	18·0	46·0	25·	Cast rod reduced 25 per cent. by forging hot. Annealed.
10·0	15·0	40·0	30·	Rolled bar.
10·0	40·0	50·0	3·	Rolled bar quenched at 900° C.

ALUMINIUM CASTINGS

OF EVERY DESCRIPTION.

We make a Speciality of Aeronautical and Automobile Work.

We are making many thousands of **Aluminium Die Castings** weekly under the celebrated **Cothias** process—in many cases **entirely eliminating** machining operations, and we hold the sole manufacturing rights in the British : Empire for this process. :

Chemical and Physical tests are made on our own premises, and our **Castings**, both **Sand** and **Die**, are produced under the most up-to-date and :: scientific methods. ::

Sole makers of the **Birmal Aluminium Pistons**, thousands of which are running to-day in a highly satisfactory manner under the most severe :: :: conditions. :: ::

Highest Class Castings to Government Specifications

ALUMINIUM

Possesses unrivalled advantages when used as

ALUMINIUM STILLS,
For Pressure or Vacuum, heated by Steam Jackets, Coils, or Direct Fire.

ALUMINIUM CONDENSERS,
Spiral, Tubular, or Atmospheric.

ALUMINIUM STORAGE TANKS,
Open or Covered.
For Beer, Milk, Oils, Essences, Fatty Acids, Nitric Acid, &c., &c.

ALUMINIUM JACKETED PANS,
Fixed or Tilting.

ALUMINIUM PRESSURE VESSELS,
Autoclaves, Storage Vessels and Transport Tanks.

ALUMINIUM BREWING PLANT,
Fermenting Vessels, Conditioning and Chilling Tanks, Storage Tanks, Yeast Plant, Bulk Transport Tanks for Road or Rail.

ALUMINIUM VARNISH PLANT,
Gum-Running Pots, Oil-Boiling Pans, Stirrers.

ALUMINIUM FUME HOODS AND PIPES. ALUMINIUM CASTINGS.

We shall be pleased to quote for, or send information about, any of the above plant on receipt of particulars of your requirements.

Our EXPERT KNOWLEDGE and EXPERIENCE are AT YOUR SERVICE

The following are tests of the 'R3' and 'R4' aluminium bronzes, manufactured by the British Aluminium Company :—

R3 Bronze.—Average breaking load, 34·04 tons ; average elongation, 21 per cent. ; maximum breaking load, 37·6 tons ; maximum elongation, 35 per cent. ; minimum breaking load, 32·8 tons ; minimum elongation, 12·5 per cent.

R4 Bronze.—Average breaking load, 41·8 tons ; average elongation, 9·75 per cent. ; maximum breaking load, 43·7 tons ; maximum elongation, 13 per cent. ; minimum breaking load, 39·8 tons ; minimum elongation, 6·5 per cent.

COPPER AND MANGANESE.

Manganese Bronze, Manganin.

The term 'manganese bronze' is applied to copper-zinc alloys of 60/40 composition to which small quantities of manganese have been added (see Manganese Bronze, p. 2558). There are, however, alloys of copper and manganese of industrial application which rightly should be admitted under this heading. The alloys of copper and manganese containing up to 5 per cent. of the latter element are harder and tougher than is copper. Those containing from 2 to 4 per cent. of manganese are frequently employed in situations where high temperatures are existent, on account of their retention of their mechanical properties under these conditions.

The following figures represent the results obtainable by stamping certain of these alloys at a red-heat (*circa* 800° C.) :—

Copper.	Manganese.	Maximum Stress.	Elongation. Per cent.
97	3	18·5	32
96	4	21·0	60

Manganin is the name applied to an alloy of copper, manganese, nickel and iron, characterised by low electrical conductivity and almost zero temperature coefficient. It is employed in the construction of electrical resistance coils. The composition is somewhat variable, but the following figures will serve to indicate its approximate analysis :—

Copper . .	80 to 84 per cent.	Nickel . . .	up to 12 per cent.
Manganese . .	4 to 15 ,,	Iron . . .	Difference.

'STELLA' ALLOYS.

'Stella' brand manganese copper is a product made by a special process which gives a thoroughly homogeneous mixture. In its preparation all impurities are removed and absolute uniformity and purity are guaranteed. The manipulation of manganese bronze castings is greatly facilitated if the manganese is introduced in the form of manganese copper, instead of ferro-manganese, owing to the fact that manganese copper melts at a lower temperature than copper, consequently overheating during alloying is impossible and uniformly good results are secured, whereas ferro-manganese will only melt at a temperature considerably above the melting point of cast iron, and in order to alloy same in the manufacture of manganese bronze a very high furnace temperature is necessary. Thus it invariably happens that the metal is considerably overheated, with the result that great harm is done to the manganese bronze, and little if any benefit is derived from the addition of the manganese.

'MAMMOTH' AND 'STORK' ALLOYS.

The 'Mammoth' alloy has great power of resistance under heavy loads, whilst 'Stork' metal has an exceptionally low friction coefficient. In one experiment 'Mammoth' metal withstood a maximum load of 4,355 lbs. with a temperature rise of 104° F., whilst 'Stella' metal withstood a load of 4,310 lbs. (rather less than that for the 'Mammoth'), but the temperature rise did not exceed 63° F. 'Stork' metal, although the load resistance did not exceed 3,025 lbs., had a temperature rise of but 59° F., the temperature rise experiments in all cases being made with equal loads.

COPPER AND NICKEL.

Cupro-nickel, Constantan, etc.

The alloys of copper and nickel containing upwards of 50 per cent. of copper are of industrial importance. The alloys may be divided into three classes.

(i) Alloys containing up to 5 per cent. of nickel and having the property of resisting high temperatures without undue deterioration. Of these alloys those containing from 2 to 3 per cent. of nickel have been employed in the manufacture of locomotive firebox tubes. Following are the mechanical properties of the 2 per cent. alloy :—

Maximum Stress.	Elongation. Per cent.	Remarks.
45·0	5·0	Hard rolled.
30·0	45·0	Hard rolled and annealed at 650° C.

Those of the 5 per cent. alloy are very similar in character.

(ii) Alloys containing from 15 to 25 per cent. of nickel and valuable on account of their ability to withstand cold working.

For the best results with these alloys only the purest metals should be employed, as small quantities of such elements as iron, silicon and sulphur are detrimental to the malleability and ductility of the resultant alloy. The maximum percentages of impurities allowable in nickel for this high-class work should be 0·050 per cent. of arsenic, 2 per cent. of cobalt, and 1·5 per cent. of other metallic impurities. The metal should be free from all unreduced oxides. Cupro-manganese, 25–50 per cent., is commonly employed as a deoxidiser in the manufacture of these nickel copper alloys, upwards of 0·25 per cent. being added to charges containing 30 per cent. of scrap. Following are the mechanical properties of the 20 per cent. alloy :—

Maximum Stress.	Elongation. Per cent.	Remarks.
40·0	5·0	Hard rolled.
20·0	35·0	Hard rolled and annealed.

The alloy containing 25 per cent. of nickel has been successfully employed in the manufacture of firebox plates.

(iii) Alloys having low electrical conductivities and whose temperature coefficients of electrical conductivity are practically nil. The 40–45 per cent. nickel alloy, known as 'constantan,' can be drawn into wire, and is employed in the construction of resistance coils and base-metal thermo-couples. Another alloy of this type, containing only 25 per cent. of nickel and 0·5 per cent. of iron, is known as 'nickeline.'

Nickel and Chromium.

Certain of the alloys of nickel and chromium now find use industrially. Of these alloys 'Nichrome,' under which trade name a number are sold, is of importance on account of its high electrical resistivity and incorrodibility. Nichrome is largely used in the manufacture of wire or electrical resistances and in the production of heat-treatment boxes, pyrometer protection tubes, crucibles. ladles, etc. Nichrome has also found use as a couple element in conjunction with Constantan (*see* above).

ALUMINIUM AND ZINC.

The alloys of aluminium and zinc are of importance as light alloys, their specific gravities varying uniformly from 2·7 to 3·3 as their zinc content increases up to 30 per cent., which may be considered the limiting percentage for those alloys of this series that may be termed 'light.' All those alloys containing upwards of 70 per cent. of aluminium are forgeable at temperatures between 300° C. and 400° C.

These alloys do not allow of their use in casting into intricate shapes, but for all plain casting purposes they are quite satisfactory. Under certain conditions these alloys corrode rapidly ; the use of high-grade spelter in their manufacture eliminates this defect. The machining properties of these alloys improve as the zinc content increases.

Below are tabulated certain of the results of tests reported by Messrs. Rosenhain and Archbutt to the Alloys Research Committee of the Institution of Mechanical Engineers.

Zinc. Approx. Per cent.	Condition of Alloy.	Yield Point. Tons per sq. in.	Max. Stress. Tons per sq. in.	Elongation. Per cent. on 2 ins.
5	1	2·70	5·20	16·0
	2	2·80	6·60	29·0
	4	4·30	7·48	33·0
11	1	6·40	9·41	8·0
	2	5·00	10·24	16·0
	3	9·42	13·78	33·0 (on 1 in.)
15	1	9·60	11·14	2·0
	2	5·80	11·69	8·5
	3	11·61	17·92	31·0 (on 1 in.)
	4	6·80	16·38	33·0
20	1	10·00	13·07	0·7
	2	7·80	13·87	4·0
	4	17·30	22·64	20·5
25	1	nil	16·26	1·0
	2	9·10	13·50	3·5
	3	20·24	24·03	27·0 (on 1 in.)
	4	25·00	27·09	16·5
30	1	11·70	16·63	1·5
	2	10·30	17·92	3·0

1. Sand-casting.
2. Chill-casting.
3. Hot-rolled bars, $\frac{1}{2}$ in. diam.
4. ditto $1\frac{1}{4}$ in. diam.

The addition of copper to certain of the aluminium-zinc alloys improves the mechanical properties of the same. The average results of certain tests on chill-castings of the aluminium-zinc-copper series are given below.

Zinc. Per cent.	Copper. Per cent.	Yield Point. Tons sq. in.	Max. Stress. Tons sq. in.	Elongation. Per cent.
19	1	9·5	14·9	5·5
19	2	12·5	16·5	5·7
20	2	10·4	14·0	3·3
20	3	11·5	16·8	4·5
20	4	10·4	15·3	3·8

OTHER ALLOYS OF ALUMINIUM.

Magnalium.

Magnalium is the name applied to a series of alloys having an aluminium-magnesium base, containing from 1·5 to 10·0 per cent. of magnesium and varying proportions of other elements, e.g. copper, tin, nickel, lead.

The table below gives the analyses of certain of these alloys, together with the uses to which they are generally put.

Use of Alloy.	Magnesium.	Copper.	Nickel.	Tin.	Lead.
Strong castings . .	1·60	1·76	1·16	nil	nil
General ditto . .	1·60	1·76	nil	traces	traces
Rolling and drawing .	1·58	0·21	nil	3·15	0·72

"Vickers' Duralumin."

"Vickers' Duralumin" is the trade name applied to a series of quaternary alloys of aluminium, copper, manganese and magnesium, containing over 90 per cent. of aluminium and possessed of high tenacity and hardness. The presence of magnesium confers the property of cumulative hardening on certain aluminium alloys—i.e. subsequent to suitable thermal treatment the hardness of the alloy increases slowly to a maximum, which is attained after several days.

Following are typical analyses of "Vickers' Duralumin":—

Copper.	Manganese.	Magnesium.	Silicon.	Iron.	Aluminium.
3·62	0·35	0·87	0·62	0·045	Diff.
3·00	1 00	2·00	—	1·000	Diff.
3·60	0·40	—	0·50	0·600	Diff.

The specific gravity varies between 2·77 and 2·84. The melting point is about 650° C. "Vickers' Duralumin" can be rolled, forged, and drawn when hot or cold. According to the purpose for which it may be required, the composition can be modified and the treatment so arranged that the material is susceptible to forging, rolling, and drawing, or it may be arranged that the greatest hardness, with corresponding smaller extension, can be produced. The following table gives a summary in which the properties of "Vickers' Duralumin" vary by such modifications in the composition and treatment.

Description of the Alloy.	Specific Gravity.	Yield Point. Tons per sq. in.	Max. Stress. Tons per sq. in.	Elongation. Per cent.	Contraction.	Brinell Hardness.
H	2·77	12·06	22·25	23	34	98
681d	2·84	16·5	29·20	18	26	125

These values are for soft rolled plates of 7 mm. thickness.

"Vickers' Duralumin" is supplied in sheets, bars, wires, strips, forgings, stampings, various sections and tubes.

Wolframinium.

Wolframinium is an alloy of tungsten, copper and aluminium. Its specific gravity (2·74) is about the same as pure aluminium; its tensile strength cast in sand 10 tons per square inch, in chills 12 to 13 tons per square inch, forged 15 tons per square inch, rolled or drawn 15 to 20 tons per square inch. Its elongation is 3 to 5 per cent. when hard, but 10 to 20 per cent. when properly annealed. It can be worked as easily as copper, can be forged, rolled, and drawn either hot or cold, takes a high polish and does not tarnish.

Romanium

Romanium is an alloy of tungsten, nickel and aluminium. Its specific gravity (2·75) is a trifle higher than that of pure aluminium, its melting point about the same, its tensile strength equal to that of Wolframinium, but it is much harder and is also of greater elasticity. It can be worked either hot or cold, forged, rolled, drawn, stamped, etc. etc. It is specially recommended for large castings, large plates and angle bars for shipbuilding and machinery.

BEARING METALS.*

The requisite properties of good bearing metals are hardness, to resist wear; strength, to bear compression; and plasticity, to allow of ready adjustment of the supported body on the bearing.

Two types of bearing metal are known:—

(*a*) Bearing metals in which the hard constituents of the alloy are distributed indiscriminately throughout a soft matrix.

(*b*) Bearing metals of spongy character; the network of the sponge being moderately hard and tough, the meshwork being soft and plastic.

These types can be grouped according to composition as follows:—

(i) Brasses and bronzes containing compounds of copper with tin, phosphorus, etc.

(ii) Bronzes containing appreciable quantities of lead.

(iii) Alloys having a tin base and containing compounds of tin with antimony, copper, etc.

(iv) Alloys having a lead base and containing compounds of tin with antimony, etc.

(v) General alloys possessed of the characteristics required of a bearing metal.

Of the above, types (i) and (ii) have been considered under the heading of 'Brass' and 'Bronze' (*q.v.*), types (iii) and (iv) are known as 'white' metals, while the majority of the alloys of type (v) can be termed 'white metals.' Of types (iii), (iv) and (v) it has been observed that metals whose atomic weight divided by their specific gravity gives a high number are good anti-friction metals, while the reverse is the case for metals which have a low quotient. Hence the use of lead and antimony for bearing alloys. In using white metal for bearings the best practice is to use the bearings wholly of white metal, discarding the cast-iron shells and using up the old bearings with the addition of a small further quantity of the more volatile constituents. White metal must be melted in a clean vessel and at as low a temperature as possible. Dross and scum in the metal tends to rapid heating in service. For the metals to be properly alloyed the high as well as the low melting points of these must be reached, but care must be taken not to overheat the alloy. For a thorough alloying a temperature of about 500° C. (930° F.) and less has been found to be sufficient. The molten metal should be stirred with a stick of pine, and a layer of charcoal always kept on the surface to prevent oxidation. The rate of cooling affects the size of the crystals and also the wearing quality. As a general rule cooling too slowly and pouring too cold produces a coarse crystal formation which is liable to heat quickly in use. In the case of the tin-antimony alloys it has been found that the best size for the tin-antimony compound cubes is 0·25 mm. edge. Pouring too hot on the other hand results in a soft metal. The shell should be heated to a temperature of 100° C. to 150° C. (212° F. to 300° F.) before pouring the metal into it, as this not only prevents blow-holes, but reduces the tendency of the lining shrinking away from the shell. The bearing should not be disturbed while the lining is solidifying, since vibration tends to enlarge the crystals and produce brittleness. The matrix of the lining should by just stiff enough to support the crystals, and the latter should be as numerous as is consistent with these, lying clear of each other and thereby causing brittleness. A Brinell hardness of 23·5 for an alloy with a lead base and 30 for a tin base has been found to give excellent results.

* See also Bearing Pressures, page 1009.

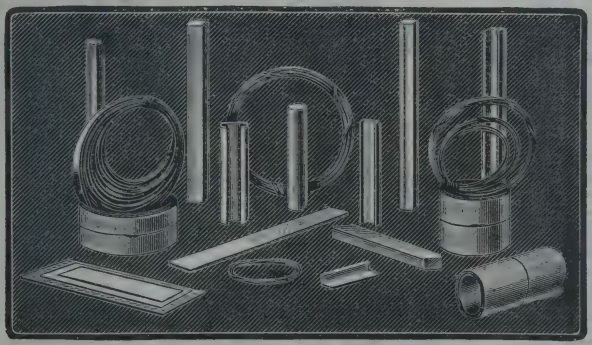
"VICKERS' DURALUMIN"

(Regd. Trade Mark)

SPECIFIC GRAVITY 2·8.

TENSILE STRENGTH UP TO 35 TONS.

AN ALLOY OF ALUMINIUM WITH THE STRENGTH AND HARDNESS OF MILD STEEL BUT HAVING ONLY ONE THIRD OF ITS WEIGHT.



It is an ideal substitute for Aluminium, Nickel Silver, Brass, Copper, Nickel-plated and Silvered Articles, and is the only substitute for Steel where Lightness combined with the Strength of that Metal is required.

For Aeroplanes, Dirigibles, Hydroplanes, Motor Car, Yacht and Boat Fittings.

For Scientific Apparatus, Instruments of precision, Orthopædic Apparatus, and Hospital Supplies, etc.

A SET OF TANK ENGINE MAIN BEARINGS & CONN. RODS

ENGINEERS · and · MANUFACTURERS · of · AERO · and · MECHANICAL · TRANSPORT · ENGINE · PARTS ·

CONN. RODS, CRANK SHAFTS etc CONN. ROD and MAIN CHAIR BEARINGS WITH STEEL, PHOSPHOR-BRONZE or GUN-METAL SHELLS, WHITE-METAL LINED. Also SOLID WHITE METAL DIE, CAST UNDER PRESSURE AT LOW TEMPERATURES, ACCURACY GUARANTEED.

SOLE MAKERS of J. RICHARDS "PLASTIC METAL" for lining all kinds of bearings.

J. H. RICHARDS & Co. SPECIALITY.

We also manufacture solid whitemetal bearings, known as **Chill Cast Bearings,** which have come much into use during the last four years for Petrol Engines, also for Gas and Oil Engines. They show a great reduction in cost over the old method of lining a gun-metal shell, with whitemetal, which required machining all over.

These Chill Cast Bearings are supplied cast exactly to size, equipped with oil holes, steady pegs, oil grooves, and backed-off at the joint, thus being quite ready to go into the hands of the engine erector.

They are produced by a very special process of our own by forcing the metal into chills while in a plastic state, and then rapidly cooled while in the chill, thus producing a dense homogeneous casting, perfectly smooth on the surface, and absolutely free from blow holes.

ALLOYS HAVING A TIN BASE.

Tin-Antimony Alloys.

These alloys, which are of type (*a*) above, are the basis of Britannia metal. The following table indicates the uses of certain of these alloys.

Tin.	Antimony.	Use of Alloy.
86	14	For seats of stop-cocks.
80	20	For plugs of stop-cocks.
79	21	Metal for bearings.
67	33	Very hard alloy, which forms the extreme limit of the ordinary tin-antimony alloys (*Hiorns*).

Babbitt, Genuine.

This alloy, whose composition is as follows,

Tin, 83·3 ; Antimony, 11·1 ; Copper, 5·6 ;

is used on important bearings under heavy loads, such as crank-shaft, crank-pin and cross-head pin journals. Closely similar alloys are employed for the axleboxes of the leading railways of the world. Several of the French railways, however, use the following alloy, which is lower in tin.

Tin, 67 ; Antimony, 22 to 11 ; Copper, 11 to 22.

Babbitt Metal, General.

In cast-iron boxes, for light work: 50 parts tin, 5 parts antimony, 1 part copper ; for heavy work : 46 parts tin, 8 parts antimony, 4 parts copper. In brass boxes: 64 parts copper, 8 parts tin, 1 part zinc. The bearing to be lined with the metal is first tinned with the Babbitt metal mixed with twice its weight of tin.

Babbitt Metal, Plastic Metal, and Phosphor Bronze.

(The Delta Metal Co. Ltd.)

These metals are supplied by the Delta Metal Co. Ltd., in various grades ; phosphor bronze is supplied in three qualities, A, B and C. The A quality is a hard bearing metal specially suitable for worm-wheels, bushes, crank pins, bearings, etc. ; B quality phosphor bronze is a bearing metal more suitable for general purposes, whilst the C grade is adapted for large pinions, worms, etc. The Co. also supply various grades of Babbit, plastic, and other lining metals, for various speeds and pressures.

Admiralty White Metal.

Tin, 86·0 ; Antimony, 8·5 ; Copper, 5·5.

ALLOYS HAVING A LEAD BASE.

Lead-Antimony Alloys.

These alloys should not contain more than 18 per cent. of antimony if they are not to be brittle. Such as do contain upwards of 18 per cent. of antimony must be given suitable support. The following table indicates the increase of Brinell hardness numbers of these alloys with increase of antimony.

Antimony. Per cent.	Brinell Hardness Number. 10 mm. 100 kilos.
2	9 approx.
5	12 ,,
10	16 ,,
15	17 ,,
20	21 ,,

The 25 per cent. antimony alloy is used by the Eastern Railroad of France as a lining for cross-head slides, rod brasses and axle-bearings.

'Magnolia'

Lead, 80; Antimony, 14; Tin, 6.
Lead, 79; Antimony, 20; Tin, Copper, etc., 1.

Other Ternary Alloys having a Lead Base.

Following is a list of ternary alloys of lead, tin and antimony, showing the mechanical properties of the same:—

No.	Lead (by difference).	Tin.	Antimony.	Yield Point. Tons per sq. in.	Tenacity. Tons per sq. in.	Elongation per cent. $l = 4\sqrt{a}$	Compression. Load in Tons required to compress to Half Length.	Brinell Hardness Number. 10 mm. ball, 200 kilos.
1	88·0	4·1	7·9	2·14	2·41	1·5	12·7	15·2

N.O.—Not observed. C.—Cracks in compression test-piece.
S.C.—Slight cracks in compression test-piece. * Failed without compression to half length.

The results contained in this table are considered sufficient to merit the following conclusions: (1) that the effect of the presence of the tin-antimony compound in these alloys is such as to render the same brittle and weak; (2) that the general mechanical properties of the lead-tin-antimony alloys containing less than about 15 per cent. of tin are improved by the addition of antimony in quantities not exceeding about 10 per cent.

Hughes recommends the following alloy for metallic packings:—

Lead, 70; Antimony, 13; Tin, 17;

while the following alloys are used as lining by the Eastern Railroad of France:—

	Lead.	Antimony.	Tin.
1	70	20	10
2	80	8	12

1. For eccentric straps and bronze slide valves.
2. Special alloys for metallic rod packing.

Ternary alloys of lead, antimony and copper are also in use. These alloys should contain from 15 to 25 per cent. of antimony and not more than 10 per cent. of copper.

Anti-Friction Alloys.

(The Delta Metal Co. Ltd.)

Delta White Antifriction Metals, Nos. IX and IXa, are used for lining bearings, bushes, etc., and are particularly suitable for heavy bearings such as those of marine engines, for railway trucks, dynamos, etc., as they do not wear, heat, or cut the journals; they are also cheap.

The application of the metals presents no difficulties whatever; the parts required to be lined should be thoroughly cleaned, and when the metal is melted (which may be done in a ladle, over a slow fire, taking care not to overheat it) it is applied in the usual way. The melting point is about 450°C.

Richards' Plastic White Metal.

The chief qualities and advantages of this metal are durability, adhesiveness, self-tinning and antifrictional properties, minimum of contraction and linear expansion when passing from the plastic to the solid state.

This alloy can be applied to many kinds of metals, including gun-metal, steel, wrought and cast iron, also aluminium, by its own self-adhesiveness, and when properly applied no abrasive force will remove it, thus dispensing with the trouble and expense of recessing or pegging, an important matter when time for repairs is limited.

It can also be used for lining up worn parts of machinery in addition to bearings. It has a low coefficient of friction, thus saving very considerably on the cost of lubrication.

Even should lubrication be neglected for a period, the metal will not run out of the bearing, but being of a plastic character, when it becomes over-heated, will simply deposit from one place to another, and thus solidify itself when in contact with lower temperatures surrounding the body of the bearing. By this means it also prevents the possibility of cutting the crankshaft or other parts that may come in contact with it.

The metal being self-tinning, no tinman's solder or tin is required to first coat the parts to be relined.

Its specific gravity being as much as 33 per cent. lighter than a lead basis alloy, less weight of metal is necessary for lining.

The metal itself has a particularly fine structure, which is attained by a special process of alloying. This structure is not affected by reheating, during its period of use, or when remelting, unless an exceedingly high temperature is attained. It can therefore be used over and over again.

This plastic metal has been extensively used for motor transport engines, aero engines, stationary engines, and pump work, for lining up bearing shells, and for die casting. It is particularly suitable for this last purpose. In order to produce solid die castings it is essential that the metal should be cast under pressure at a low temperature so as to preclude, by the retention of the metal as a solid rather than a fluid, the possibility of air holes and segregation of the alloy.

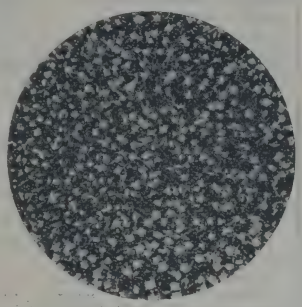

Fig. 36.—Micrograph of Richards' Plastic Metal (Magnified 50 Diameters).

Richards' Plastic White Metal lends itself to these conditions. After prolonged trials it has been found that bearings made by this process are eminently suited to the onerous duties to which aircraft bearings are subjected.

The manufacturers of this alloy and bearings are Messrs. J. H. Richards & Co. Ltd., Cato Street North, Saltley, Birmingham.

Hoyt's Metals.

Hoyt's Standard Babbitt or Anti-friction Metals are made in eight qualities, this range being sufficient to meet the conditions in every class of machinery. The two highest qualities are 'Number Eleven' Alloy and the I.C.E. ('Internal Combustion Engine') Brand.

'Number Eleven' Alloy was, during the war, largely used for the bearings of aircraft engines, nearly 800 tons being supplied in 1918 for this purpose alone. This metal is also stated to give excellent results in the bearings of automobile engines, marine petrol and oil engines, steam turbines, marine steam engines, Diesel engines, etc. Its specific gravity is 7·34, the weight per cubic inch being ·268 lbs. Approximately 100 lbs. of 'Number Eleven' Alloy will go as far as 113 lbs. of a high-grade metal of, say, 8·5 specific gravity.

'Number Eleven' Alloy is in use by the British Admiralty for certain important work. It is of higher quality than the Air Ministry's *Specification L.* 9 for Anti-friction Metal for Aviation Engines.

The I.C.E. ('Internal Combustion Engine') Brand has been used extensively for many years be British and Continental motor-car manufacturers. It was used during the war by the British Army Mechanical Transport, the I.C.E. Brand being adopted as standard after many tests. The metal is largely used for high-speed steam engines, locomotives, steam pumps, marine engines, air compressors, etc.

Miscellaneous Metals for Bearings and Engine Parts.

The following special mixtures are stated to be satisfactory for the duty mentioned:—

ZINC-TIN ALLOYS.

Zinc and tin form a series of eutectiferous alloys, some of which are of value as bearing metals. The alloys, in common with all bearing metals, are very susceptible to differences in casting

temperature, as may be gathered from the following table, which gives in detail the effect of varying the temperature of casting an alloy of 70 per cent. of zinc and 30 per cent. of tin :—

Casting Temperature.	Maximum Stress.	Elongation. Per cent.	Stress to compress to half length.
525° C.	5·09	3·0	7·7
500° C.	6·17	3·0	13·6
475° C.	6·56	8·0	15·4
450° C.	7·37	17·5	14·8
425° C.	7·37	35·5	15·0
400° C.	7·24	20·0	15·8

The above figures are for chill castings.

The alloys of zinc and tin containing from 25 to 75 per cent. of zinc possess, when in the chill cast condition, tenacities varying from 6·0 to 6·5 tons per square inch, percentage elongations varying from 30 to 45, and are compressible to half-length under stresses (calculated on the original areas of the test-pieces) varying from 13 to 17 tons per square inch. The eutectic melts at about 200° C. and contains 16 atomic per cent. of zinc.

In order that these alloys may approximate more closely to type A (*q.v.*) bearing metal, the zinc-tin series containing no relatively hard constituent, copper and antimony are frequently added. The addition of one or both of these constituents results in the formation of a bearing metal in which the hard compounds of antimony and zinc, etc., are indiscriminately distributed throughout the eutectiferous matrix. The following are analyses of certain alloys of this type :—

Zinc.	Tin.	Copper.	Antimony.	Use of Alloy.
80	14·5	5·5	—	Fenton's alloy for locomotive axle-boxes.
69	26·0	5·0	—	Propeller bush.
88	2·0	8·0	2·0	Bearing metal for general use.

In this connection it may be noted that ternary alloys generally are far preferable to complicated mixtures and usually fulfil all the requirements of good bearing metals.

A French report on new anti-friction metals includes trials of alloys consisting chiefly of aluminium, cadmium, magnesium, and especially of zinc. Such alloys were designed to reduce as far as possible the use of copper, tin, lead, and antimony, and the most satisfactory results are stated to have been given by a compound of 63·3 per cent. of zinc, 21·3 per cent. of tin, 12 per cent. of lead, and 3·3 per cent. of copper.

FUSIBLE METALS.

With the following combinations of metals, which form 'eutectiferous' alloys, it is possible to prepare an alloy having a melting point lower than that of any member of the series.

Series.	Alloy with Lowest Melting Point (Eutectic).	Melting Point.
Bismuth-lead	57·4 per cent. Bismuth	124·5° C.
Bismuth-tin	56·7 „ „	137° C.
Bismuth-cadmium	60 „ „	146° C.
Cadmium-tin	52 „ Cadmium	177° C.
Lead-tin	36·5 „ Lead	180° C.
Cadmium-lead	17·4 „ Cadmium	247·3° C.

By the addition of one or both of the residual metals to any of the above combinations, systems of ternary and quaternary alloys, having individual members with melting points lower than those of all other members of these systems and less than those of the eutectics given above, may be obtained. These ternary and quaternary alloys are the true 'fusible metals.'

The alloys of lead, tin and bismuth are of value for the following purposes :—

(i) The manufacture of casts of delicate objects that would be damaged if subjected to high temperatures. The following alloys are recommended for this purpose :—

Bismuth	59·2	50·0	50·0	50·0
Lead	27·3	31·2	30·0	25·0
Tin	13·5	18·8	20·0	25·0

These alloys expand considerably on cooling and are valuable also for the taking of impressions from dies, medals, etc.

(ii) Fusion pyrometers. Parkes and Martin recommend the following fusible metals as pyrometers for the tempering of steel tools. The article to be treated is placed on a plate of the alloy, which is heated till it melts. The tool, being then in the required condition, is quenched in water.

TABLE OF MELTING POINT OF BISMUTH-LEAD-TIN ALLOYS.

Bismuth.	Lead.	Tin.	Melting Pt.	Bismuth.	Lead.	Tin.	Melting Pt.
50·0	31·2	18·8	94° C.	16·6	33·2	50·2	158° C.
47·0	35·5	17·7	98° C.	16·0	36·0	48·0	155° C.
42·1	42·1	15·8	108° C.	15·3	38·8	45·9	154° C.
40·0	40·0	20·0	113° C.	14·8	40·2	45·0	153° C.
36·5	36·5	27·0	117° C.	14·0	43·0	43·0	154° C.
33·3	33·3	33·3	123° C.	13·7	44·8	41·5	160° C.
30·8	38·4	30·8	130° C.	13·3	46·6	40·1	165° C.
28·5	43·0	28·5	132° C.	12·8	49·0	38·2	172° C.
25·0	50·0	25·0	149° C.	12·5	50·0	37·5	178° C.
23·5	47·0	29·5	151° C.	11·7	46·8	41·5	167° C.
22·2	44·4	33·4	143° C.	11·4	45·6	43·0	165° C.
21·0	42·0	57·0	143° C.	11·2	44·4	44·4	160° C.
20·0	40·0	40·0	145° C.	10·8	43·2	46·0	159° C.
19·0	38·0	43·0	148° C.	10·5	42·0	47·5	160° C.
18·1	36·2	45·7	151° C.	10·2	41·0	49·5	161° C.
17·3	34·6	48·1	155° C.	10·0	40·0	50·0	162° C.

(iii) Soft solders. For the union of metal to glass, e.g. in the manufacture of paraffin lamps, the following alloy has been suggested :—

Lead, 40·0 ; Bismuth, 33·4 ; Tin, 26·6.

(iv) Fusible plugs.

The above alloys are nearly all of a brittle character. For the manufacture of ductile fusible the alloys use of cadmium in place of bismuth is recommended.

The following table includes the best known of the other fusible metals :—

Alloy.	Cadmium.	Lead.	Tin.	Bismuth.	Melting Pt.
Fusible alloy . .	12·5	25·0	12·5	50·0	55·5° C.
Lipowitz's alloy . .	10·0	26·6	13·3	50·0	60–68° C.
Woods' alloy . .	15·4	30·8	15·4	38·4	71° C.
Fusible alloy . .	34·5	27·5	10	27·5	75° C.

Spence's Metal.

This compound is obtained by melting the three sulphides of iron, zinc and lead with sulphur. The product is a dark grey mass of great tenacity, small power of conducting heat, a specific gravity of 3·4, a melting point of 160° C. In congealing it expands like bismuth and type metal, and resists in a remarkable degree the action of atmospheric influences, alkalies and acids, even of aquaregia, its surface scarcely being affected after having been exposed to the action of the latter for four weeks. Its property of expanding in congealing, and therefore filling completely all depressions of the mould, makes it particularly available for castings. If the compound is poured on a plate on which the impression of the hand has been made, the cast will show all the lines and the pores of the palm.

The metal has been used for jointing gas and water pipes.

For further particulars see Patent Specification No. 2706, 1879.

Non-Magnetic Alloys.

These alloys are used as substitutes for steel wherever it is employed in the works of watches. The composition of the alloys varies from 45 to 75 parts of palladium, 15 to 30 parts of copper, 20 to 25 parts of silver, with sometimes the addition of small proportions of iron, steel, nickel, gold and platinum. These alloys are claimed to be unoxidisable in moist air, to preserve their elasticity indefinitely, not to vary sensibly with changes of temperature, and to remain uninfluenced by proximity to dynamos.

Another non-magnetic alloy, recently brought out by Messrs. Ostermann & Lacroix, of Geneva, Switzerland, is made of from 30 to 40 parts of gold, 30 to 40 parts of palladium, 0·1 to 5 parts of

rhodium, 10 to 20 parts of copper, 0·1 to 5 parts of manganese, and the same proportions of silver and platinum. The copper and manganese are first mixed, after which the other articles are added; or all the metals may be put into a crucible at the same time, the manganese being used for the bottom layer.

A non-magnetic variety of 'Bull's Metal' is manufactured and sold as No. III. and is being adopted for funnels and other erections of warships where the material must possess the mechanical properties of steel without its magnetic influence.

The Delta Metal Co. Ltd., supply under their "Delta" Brand non-magnetic metals (bronze and brass) to meet special requirements.

SOLDERS AND SOLDERING.

The following notes are published with the kind permission of the Editor of 'The Metal Industry.' (See 'The Metal Industry,' vol. 9, No. 4.)

Points to be Observed for Successful Soldering.

Attention should be paid to the following points if success is to be attained in soldering or brazing :—

1. In the preparation of the solder, uniformity of composition should be aimed at. Readily volatile or oxidisable constituents should be retained.

2. In the choice of the solder, consideration should be taken of the fusibility of the solder. The melting point of the solder should be less than that of the metal to be soldered. It should be noted, however. that the more nearly the melting point of the solder approaches that of the metal to be soldered the better is the union obtained, although the more difficult is the operation of soldering. It should be considered whether the solder will mingle perfectly with the surfaces to be united. One having mechanical and physical properties as nearly as possible approximating to those of the metals to be united should be used. One whose mechanical and physical properties will not be subsequently modified by any treatment—thermal or otherwise—should be employed.

3. In the operation of soldering, thorough mechanical and chemical cleanliness of the surfaces to be united must be obtained, e.g. by scraping, filing, grinding, etc., and by dipping in suitable chemical reagents. A source of heat both smokeless and sufficiently hot to raise the temperature of the sections to be united above the melting point of the solder is necessary. A suitable flux must be used.

Fluxes.

Fluxes are used to protect the surfaces of the metal to be united from the oxidising action of the atmosphere during the process of heating. The presence of any non-metallic materials, such as oxides or carbonates, on the surfaces to be joined, effectually prohibits perfect union. As the process of heating a metal in the air always leads to the formation of a film of oxide on its surface means must be employed to protect the surface. Use is made of readily fusible salts and of oils that are non-volatile at the temperature of soldering for this purpose. For hard-soldering borax is practically the only flux employed. It is applied as a paste with a brush to the surfaces of small articles, and as a powder to those of larger articles. For soft-soldering a variety of materials is used, the following list giving the most important of these, together with their uses.

(i) Zinc chloride is used for the soldering of sheet metal, copper alloys and bright iron. It is poisonous and corrosive, and is on these accounts unsuited (*a*) for the soldering of tins destined to contain food, and (*b*) for the production of delicate work, e.g. electric fuses.

Zinc Chloride Solution.

Kill 2 quarts hydrochloric acid with all the zinc it will take up. Add a quart of water or add part until zinc is fairly dissolved. A quart of glycerine which has been mixed with a quart of alcohol is then added to the solution.

This fluid is used for all kinds of soldering, especially with greasy and dirty connections and iron. It is claimed that glycerine prevents rust, which plays havoc with other soldering solutions containing hydrochloric acid. (*Street Railway Journal.*)

Zinc Chloride Paste.

1 lb. vaseline or petrolatum ; 1 oz. (fluid) saturated solution of chloride of zinc.

The use of petrolatum instead of vaseline is recommended. While they are identical in composition, the name 'vaseline' is registered as a trade-mark, and commands a higher price on this account. Petrolatum is much cheaper. The chloride of zinc solution is made by dissolving as much zinc in strong muriatic acid as it will take up. An excess of zinc should be present, and all the acid neutralised. This will form a thick, oily solution. The petrolatum and chloride of zinc are mixed and thoroughly incorporated by means of a mortar and pestle or by vigorous stirring. The advantage of this soldering paste lies in the fact that it does not spatter and is not corrosive.

(ii) Ammonium chloride is used as a flux when soldering copper and iron.

(iii) Ammonium phosphate is used when treating with tin, zinc, copper and brass ware. It is non-corrosive and non-poisonous, but is somewhat refractory.

(iv) Hydrochloric acid is employed when dealing with zinc and zinc-coated ware.

(v) Lactic acid is useful in connection with copper and its alloys, but has the disadvantage of producing a tarnish on the surfaces adjacent to the soldered surfaces.

(vi) Venice turpentine and Gallipoli oil are used (separately) when soldering pewter or Britannia metal.

(vii) Russian tallow is employed when soldering heavy lead work.

(viii) Palm oil is employed in the treatment of light lead work.

(ix) Resin is an advantageous flux when subsequent corrosion is likely to be deleterious. It is used on soft alloys and tinware.

Hard Solders.

The hard solders may be divided into two groups, each of which will be considered separately in succeeding paragraphs—brazing or 'spelter' solders and silver solders.

Brazing or 'Spelter' Solders.

The basis of the brazing or 'spelter' solders ('spelters' they are commonly called) is brass. As the percentage of zinc is increased in the brasses so does their utility as solders for the more readily fusible metals and alloys increase. There is, however, a limit beyond which the addition of zinc to these alloys serves no useful purpose, owing to the fact that the resulting alloys are, on account of their brittleness and weakness, of no practical value. This limiting value is at about 45 per cent. of zinc. The particular alloy which is in most general use contains 50 per cent. of zinc and melts at about 875° C. (1607° F.). It is employed in brazing general brass work, which is possessed of melting points varying from about 890° C. (1634° F.) to about 1000° C. (1832° F.). For brazing metals, etc., having higher melting points than the above, brasses containing a less percentage of zinc are used. Thus, for the soldering of general ironwork the brass containing 35 per cent. of zinc is used, while for the brazing of copper and light ironwork that having 40 per cent. of zinc is employed. The most malleable solder contains some 30 per cent of zinc, but its refractory nature somewhat subtracts from its value.

For certain purposes, the above alloys, owing to their yellow colour, are prohibited. Occasionally—e.g. in the brazing of nickel silver and iron—whiter alloys are required. For this purpose alloys containing nickel are employed, of which the following are examples :—

Copper per cent.	Zinc per cent.	Nickel per cent.
37·50	50·00	12·50
35·00	57·00	8·00

Other white solders, for use in the brazing of brass and more fusible than 'spelters,' contain a percentage of tin. Two such solders are given below :—

Copper per cent.	Zinc per cent.	Tin per cent.
43·34	6·66	50·00
57·50	25·00	17·50

Silver Solders.

Silver solders are employed for soldering gold, silver, copper, iron, and their alloys, the flux generally used being borax, though with very hard solders—i.e. solders having high melting points—powdered glass is sometimes of value.

Such as are suitable for general soldering and brazing, and containing an excess of base metal. are tabulated below :—

Copper per cent.	Silver per cent.	Zinc per cent.	Uses.
90—95	10—5	—	Solder for thin sheets of mild steel.
55·0	45·0	—	Alloy for instrument-makers; tough and fluid
50·0	30·0	20·0	Solder for small brass work.
46·0	38·5	15·5	Solder for bronze and nickel silver.
43·0	9·0	48·0	Solder for general work on copper alloys.

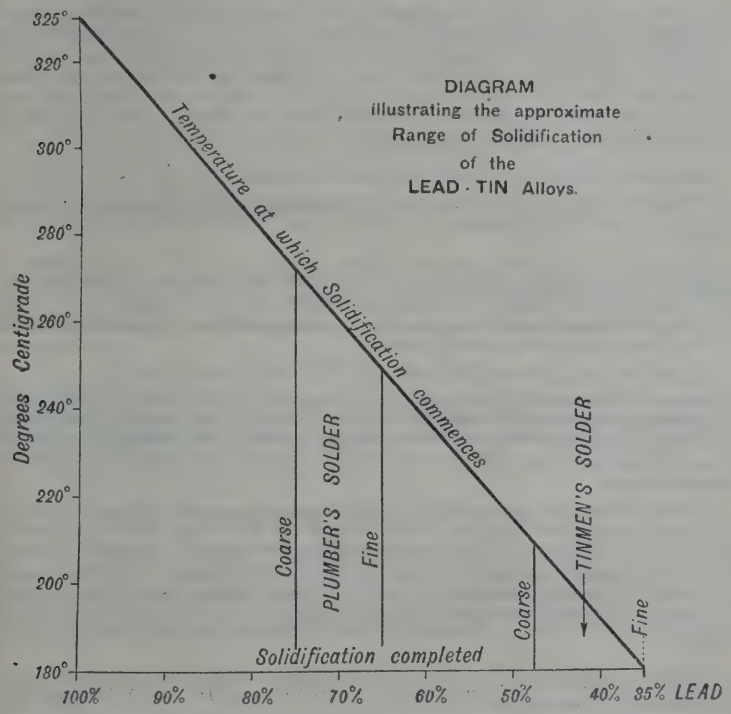
Tin-Lead Solders.

Tin and lead form a series of alloys, of which only those containing upwards of 35 per cent. of lead are employed as solders. These alloys may be divided into two classes, those that solidify at practically one definite temperature and those which are pasty over a considerable range of temperature before they become completely solid. The former are used as tinmen's solders, the latter as plumbers' solders, their value to each of these craftsmen being dependent on the properties associated with their solidification already mentioned. The diagram on page 2579 indicates the ranges of composition of the two types of solder already mentioned.

It will be seen that fine tinmen's solder solidifies at a definite temperature of 180° C. (356° F.) while coarse tinmen's solder commences to solidify at about 209° C. (408° F.), passes through a

pasty stage, and finally completely solidifies at 180° C. (356° F.). Soft solder is the name given to the alloy containing 50 per cent. of lead, whilst the fine plumbers' solder, used in making 'wiped' joints, which commences to solidify at about 250° C. (482° F.), contains 66·6 per cent. of lead. A solder frequently used for the union of tinplate contains about 90·0 per cent. of lead, and hence has a very marked pasty range of temperature.

The appearance of the tin-lead solders affords some idea as to their value. The surface of good solder should be smooth and even, and rectangular castings of the same should have a distinct furrow along the centre of their upper surface. The presence of zinc, though only traces of this metal be present, causes the free surface of the solder to become minutely crystalline.



Bismuth, copper, and silver do not affect the surface condition of solders when present in quantities varying from 0·2 per cent. in the case of the last metal to 1·0 per cent. in the case of the first, while antimony up to 2·0 per cent. improves, rather than otherwise, the surface condition. The presence of any of these elements leads to a reduction of the melting point of the solder.

To prevent hot solder sticking to work mix common whiting or cold-water paint with wood alcohol, and paint the part that is to be protected. The hot solder will not stick, even if the piece is held in the melted alloy. Water will do as well as alcohol to mix the paint; but alcohol is the most convenient, inasmuch as it can be used without waiting for the paint to dry. If water is used the paint must be thoroughly dry, as otherwise the moisture will cause the solder to fly.

Bismuth Solders.

These solders are alloys of bismuth, tin and lead, and are in general more fusible than the tin-lead solders. The useful alloys contain from 20 per cent. to 65 per cent. of lead, from 12 per cent. to 55 per cent. of tin, and from 12 per cent. to 55 per cent. of bismuth. The alloys containing the higher percentages of bismuth are the most fusible of these solders, which are employed for general pewtering. The solder containing about 50 per cent. of bismuth and 20 per cent. of tin has the lowest melting point of the series, its value being 96° C. (205° F.).

Aluminium Soldering.

The only process that can be recommended for the uniting of aluminium when the union is to be possessed of strength and durability is welding (see p. 2601). In certain instances the soldering of aluminium to itself or to other metals may, however, be resorted to. The process of soldering is considerably cheaper than is that of welding, and this, of itself, is worthy of consideration. The soldering of aluminium, however, presents numerous disadvantages owing (i) to the ready oxidation of aluminium and the difficulty of removing the oxide formed when the metal is heated, and (ii) to the rapid disintegration under the influence of moisture of soldered joints owing to the electropositive nature of aluminium with respect to those metals that may be usefully employed in the manufacture of solders.

The aluminium solders may be divided into four main groups.

1. Alloys having an aluminium-zinc base and containing varying proportions of copper. These alloys contain from 50 per cent. to 95 per cent. of zinc and from 5 per cent. to 30 per cent. of copper.

2. Alloys having a zinc-tin base and containing small proportions of such elements as aluminium (up to 12·5 per cent.), copper (up to 2·5 per cent.), phosphorus (in traces), etc. These alloys contain from 30 per cent. to 80 per cent of tin..

3. Alloys of cadmium and zinc or possessed of a cadmium-zinc base. The cadmium content in these alloys rarely, if ever, exceeds 30 per cent.

4. Alloys that are members of none of the above well defined groups of alloys.

Of group 1 solders, those aluminium-zinc alloys, containing from 3 per cent. to 30 per cent. of aluminium, have been largely employed for general soldering. For light aluminium work, where somewhat stronger solders are required, an alloy consisting of 80 per cent. of zinc, 12 per cent. of aluminium, and 8 per cent. of copper has been found to be of value, while for heavier aluminium work a solder containing 90 per cent. of zinc, 6 per cent. of aluminium, and 4 per cent. of copper is useful.

Of group 2 solders, the most satisfactory alloy (according to the *Iron Age*) consists of 69 per cent. tin, 2·5 per cent. of 10 per cent. phosphor tin, 26 per cent. of zinc, and 2·5 per cent. of aluminium. To avoid loss of the more easily volatile of these metals, the aluminium is melted first, zinc is then added in small pieces, then tin in small pieces, and lastly the phosphor tin. No acid is used, the solder being self-fluxing, but the surfaces to be soldered or joined are covered with a thin coat of solder in the usual way, and then brought together, heated with a soldering copper (iron), blow-pipe, or torch, until the solder already upon them is melted, when pressure is applied and the joint is made. The aluminium must be heated to about 660° F. before it can be soldered.

Of group 3 solders, it can be stated that most satisfactory results have been obtained with the alloys of cadmium and zinc containing from 20 per cent. to 30 per cent. of cadmium, both as regards strength and durability.

In preparing aluminium for soldering, the parts to be united must first be scraped or filed in order that the thin skin of oxide always present on aluminium that has been exposed to the atmosphere may be completely removed.

It is scarcely necessary to state that all oil, grease, or organic matter must be completely removed from the parts to be soldered. In practically all cases solders for aluminium are best applied without a flux. Generally speaking, the process of soldering aluminium is identical with that of ordinary soft soldering. It is well, however, in the case of aluminium soldering, to heat the parts to be united until the solder will just melt upon the surfaces to be joined and then to rub the solder into the metal with a wire brush or rod, in order that intimate contact may be made between the solder and the metal to be soldered. The strength of the joint depends to a large extent on the thoroughness with which this preliminary treatment is conducted. Soldering is then continued in the usual manner.

Cold Solder (Amalgam Solder).

By shaking finely-divided copper with mercury in a little dilute sulphuric acid an amalgam can be prepared which may be used to unite joints at ordinary temperatures. The amalgam is formed into pellets, which are heated till mercury begins to exude from the surface. These pellets are wiped free from mercury and are then rubbed to a soft paste in a mortar. The surfaces to be united are first treated with sodium amalgam (sodium 2 per cent.), the soft paste of copper amalgam being then applied. The surfaces to be joined are then tightly pressed together, the union being completed in about three hours.

Soldering Aluminium Bronze.

To solder aluminium bronze with ordinary soft (pewter) solder: Cleanse well the parts to be joined from dirt and grease. Then place the parts to be soldered in a strong solution of sulphate of copper, and place in the bath a rod of soft iron, touching the parts to be joined. After a while a copper-like surface will be seen on the metal. Remove from bath, rinse quite clean, and brighten the surfaces. These surfaces can then be tinned by using a fluid consisting of zinc dissolved in hydrochloric acid in the ordinary way with common soft solder. If the surface is not coppered an aluminium alloy must be used.

Soldering Cast Iron.

(1.)

If the part of iron to be soldered is cast iron that is hard and thin, it should be polished on an emery wheel and made clean and bright. Then dip it in potash water, after which dip it for an instant in clean water, and wash quickly with undiluted hydrochloric acid of the ordinary strength; go over it with powdered resin and solder made from half tin and half lead. This must be done quickly, before the surface has time to dry.

(2)

File the surface clean, and wash as before; wipe it over with a flux made of sheet zinc dissolved in hydrochloric acid until it is surcharged, or is a saturated solution and has been diluted with its own quantity of water; then sprinkle powdered sal ammoniac on it, and heat it on a charcoal fire until the sal ammoniac smokes. Dip it in melted tin, and then remove, and rap off the surplus tin.

To solder Metal to Glass.

Coat metal with platinum, and fuse latter to glass. Paint glass, after warming with neutralised solution of chloride of platinum mixed with essential oil of camomile. Heat gently till oil is expelled, and then raise temperature to dark red heat; the chloride becomes reduced, and platinum is deposited on the glass. The platinum or layer of copper is deposited by electro-deposition. To this layer metals can be soldered.

CASTING AND FOUNDING.

Moulding-sand.

(1.)

1 cubic foot sharply burnt and pulverised pure fire-clay; 60 cubic inches sugar; 2 quarts water; ½ quart paraffin oil. No lime or charcoal must be included in the mixture. Thoroughly mix. Suitable for castings of ingot iron.

(2.)

93 parts pure quartz sand; 7 parts clay free from lime; the latter acts as a cement for the formrr.

(3.)

For small castings:—Red sand, 3 parts by measure; coal dust (finely sifted), 1 part by measure.

(4.)

For large castings:—Red sand, 3 parts by measure; coal dust (finely sifted), 1 part by measure; chopped straw, or dried horse manure, ¼ part by measure.

The latter makes the sand light and porous, facilitating the release of the gases. As the sand becomes impoverished by being burnt, the coal dust is renewed from time to time. If paraffin is used to damp the mould, black sand will bind and can then be dried as when red sand is used.

Moulding-sand which has partially lost its cementing power may have it restored by mixing with fresh sand.

Green, or floor sand that has ' gone dead ' (dehydrated) is frequently revived with Birmingham or Mansfield sand. Bunter sand, and also Barrow sand, have been found very good for the same purpose.

When the metal touches the clay bond the clay is undoubtedly killed, but not so the ferruginous bond, and long-life sand is generally rich in the latter.

Ferruginous bond in moulding sand is usually the cause of the production of a smooth, sound surface to the casting, particularly in the case of steel. In non-ferrous practice it is usual to ensure the smoothness of the skin by painting the surface of the mould or ' facing ' it with a layer of finer sand (facing sand) or a wash.

The washes used for painting the mould in non-ferrous work have usually either china clay or a graphitic substance as base. Graphite (plumbago) is itself used at other times. ' Scotch blacking,' which is a mixture of charcoal and graphite, is employed.

A suspension of the powder in water may be assisted by the addition of a little borax or molasses.

Cores.

For the making of ' cores ' in British foundries a ' compo ' moulding sand is made from ordinary sand such as Mansfield and broken fragments of graphite crucibles ground and mixed.

The admixture of the coarser material ensures good venting of cores; at times the sand alone is used.

Oil-bonded cores (where the oil is generally a commercial linseed, such as ' Baltic seed oil '), unlike those used in steel founding, have not met with much success in non-ferrous founding at home, but are adopted extensively in America, where a fairly coarse high-silica sand is the base. Sands from Lumberton and Howell, N.J., are so used. (*Horobin.*)

Testing Moulding Sands.

For general handiness and practicability, test tubes of 35 mm. (1⅜ ins.) internal diameter and 230 mm. (9 ins.) long may be employed. The sand to be examined is slowly dried and passed through a 12-mesh sieve, fed into the test tube slowly through a funnel, and gently shaken to a level of 3 ins. above the bottom of the tube. Tap water, cooled to 15° Cent. after boiling, is poured into the tube, covering the sand by a depth of 4 ins. The water and sand are then vigorously shaken by hand, a method found more effective than mechanical stirring or whirling, and yielding more regular results. After shaking, the sand is allowed to settle in the vertical tube for, say, five minutes, when the water level will be found to have subsided by a definite amount, the new level remaining constant. The volume represented by the fall in the water level is a measure of the voids between the sand, silt, and clay grains, and furnishes an index of the type and openness of the grain packing, and also approximately of the gas permeability of the sand.

The tube is next filled to the brim with water at 15° Cent. and shaken as before until, by a similar indication, mixture is effected. At the moment of complete mixture of the water and sand the tube is held vertically, and the time taken for the fall of the sand grades (C.S., M.S., and F.S.), the level of which rises until the sedimentation of these grades is complete, is noted. The moment chosen for the up-ending of the tube and its contents is the time taken as the commencement of the test, and the time taken for the subsidence of the sand grades affords a measure of the mean size of the grains in these grades. With some sands it is possible to time the sedimentation of two or three distinct grain sizes in this first subsidence.

(*J. E. Fletcher.*)

To repair Castings by Burning on.

A piece of machine-framing, the necks of rolls, or a standard which has been broken or found defective, may be repaired as follows: First cut away the defective parts down to the sound metal; build a coke fire round the part of the casting which is to be repaired until it is brought to a bright red-heat, then dust over the surface of the cut metal with powdered glass or borax. Then apply a hollow loam mould of the desired part to the casting, properly secured in position and provided with a hole for the exit of the metal. Pour very hot liquid cast iron into the mould, and allow it to flow away until the cut surface of the original metal of the casting can be felt with an iron bar to have become soft and pasty by contact with the hot liquid iron. Then stop the exit hole and allow the metal in the mould to set. If the operation has been properly performed the casting should, when struck, ring with the same sound as a single good casting, thus showing that the old and new metal are perfectly united.

Sealing up Cracks in Castings and Cementing Joints.

Cracks in the walls of pressure vessels may be patched by bolting on a plate with a thickness of sal ammoniac and iron borings beneath it. Many an external firebox sheet has been patched in this way.

A cast-iron cylinder for a hydraulic press in which the iron was so porous that, under 2,000 lb. pressure, the water ran down the outside in rivulets, has been sealed by filling the cylinder with water containing a large quantity of sal ammoniac and letting it stand for a couple of days. At the end of that time the cylinder was perfectly tight.

The sal ammoniac treatment has been used in railway shops for stopping cracks in bushing cylinders. In one instance an 18 × 22 in. cylinder was patched that way. It was an old cylinder that had been bored out and a cast-iron bushing inserted. A coat of white lead was spread on the outside of the bushing and after it was in place it was stayed to the cylinder wall by drilling holes through the wall and bushing and screwing in brass plugs. Some time later a crack running lengthwise between the plugs in the outer shell opened up for about 15 in. This was made tight by removing the piston, closing the ends of the cylinder and pouring a sal ammoniac solution through the ports until the cylinder was full. This was allowed to stand for ten days, then the cylinder was drained and refilled with a weak solution of muriatic acid and allowed to stand again for about ten hours. The purpose of the muriatic-acid solution was to complete the work begun by the sal ammoniac. It was presumed that the acid would cut away the coating of rust produced by the sal ammoniac, and that the particles would gravitate toward the pressure. And apparently this is what happened.

White lead has been used with advantage in making up threaded pipe joints and when pressing the brasses into locomotive driving boxes, placing driving pins in the wheels, etc. In the latter case the white lead acts as a lubricant while the job is being done, and later on, after it has set, it serves to cement the part pressed in. For many uses red lead is preferable to white, and next to litharge, is best for holding anything. If a threaded pipe joint is made up, say a 2 in., with white lead, after a year's time it will still be possible to remove the fitting, but if the same fitting is made up with red lead, and it is desired to take it off after the lead has hardened, the fitting will have to be broken unless sufficient heat can be applied to cause it to loosen from the pipe.

There is no cementing effect when graphite and oil is used on a pipe thread. With graphite and oil on a thread a fitting can be made up tighter than would otherwise be possible. Also, the graphite is squeezed compactly into the interstices in the joint and its very compactness holds it against blowing out under pressure, but it does not anchor the fitting. Therefore, no greater stress is necessary to remove the fitting at any time than was used to put it on.

Litharge will make a threaded pipe joint absolutely leak-proof against any kind of fluid and against any pressure that the pipe will stand.

(*Power*, *July* 1, 1924.)

Pattern Composition.

A composition that has many advantages over wood for making small patterns can be made as follows:—With hot water mix into a thick paste three parts by volume of starch, one part ground glue, two parts fine resinous sawdust. The sawdust should not be added until the starch and glue have been dissolved by the water. After the ingredients are thoroughly mixed, heat the whole to 190° F., and continue the heating until the whole becomes a hard mass, then allow to cool, and remove from the receptacle. The resulting composition is a strong, hard, horn-like substance, that can be machined, sand-papered and varnished just as can wood. The principal advantages of this composition over wood lie in the fact that it has no grain, and therefore turned and complicated patterns made from it do not have to be built up or glued together, and that for the same reason it is easier to turn and machine, and offers a smoother surface when finished. It is also more fireproof than wood and not so readily affected by atmospheric changes.

(*American Machinist.*)

Shrinkage of Castings.

The allowance for shrinking in casting should be for each foot in length:—

	Parts of an Inch.			Parts of an Inch.	
For cast-iron pipes	·125	= $\frac{1}{8}$	Brass	·17	= $\frac{3}{16}$
„ beams and girders	·1	= $\frac{1}{10}$	Lead	·31	= $\frac{5}{16}$
„ cylinders, large	·094	= $\frac{3}{32}$	Zinc	·25	= $\frac{1}{4}$
„ „ small	·06	= $\frac{1}{16}$	Copper	·17	= $\frac{3}{16}$
In thick breadth	·156	= $\frac{5}{32}$	Tin	·25	= $\frac{1}{4}$
In thin breadth	·156	= $\frac{5}{32}$	Bismuth	·156	= $\frac{5}{32}$

Cleaning Castings.

A large proportion of the loose sand on castings may be removed in the 'tumbling' process, but the adhering sand and scale of oxide, which soon destroy the cutting edge of the tools, are best reduced by a pickle; the following have met with general approval.

Sulphuric Acid Pickle.—Ordinary commercial sulphuric acid and water in the proportion of 1 of the former to 30 of the latter. In this case the castings are required to remain in the pickle for about 10 hours, and are then washed with hot water to remove all trace of the acid and prevent rusting.

Hydrofluoric Acid Pickle.—This acid is slower in its action and not so liable to cause corrosion as the above. The castings, however, should be first tumbled in order to remove loose sand (as the sand neutralises the solution very much more quickly than the iron) and then immersed in a mixture containing 1 of hydrofluoric acid to 15 of water. The bath should be maintained at a temperature of 120°F. by a steam coil. The castings are then washed in clean hot water and sometimes in hot water with a small proportion of lime (about 1 lb. of lime to 8 gallons of water). The baths are best made of oak, wood pinned, with no exposed metal fastenings and well lined with asphaltum. The attendant should be furnished with wooden clogs, strong leather apron and rubber gloves to protect him from the acid.

The acid should be added *very slowly* to the *water* and well stirred in the process. Never add the water to the acid, otherwise the acid vapour will be carried all over the place.

An American factory is using high-pressure water for cleansing castings of sand and cores. A centrifugal pump, driven by a 50-h.p. motor, delivers 250 gallons per minute at a pressure of 250 lb. per sq. in., and the work is carried on in a closed chamber with glass windows. It is said that a casting which previously took a whole day to clean can be finished with the water jet in half an hour.

(See also 'Lubrication Troubles,' p. 1028.)

Dips for Castings.

Special for Electro-galvanising.—For preparing work for electro-galvanising the following can be used with advantage, but for no other solution except, perhaps, copper: Add to the dilute acid ½ lb. of sheet zinc to each 25 gals. of solution, adding additional amount occasionally as it works out.

Bright Dip for Iron.—Work that has been pickled in the ordinary way to remove sand and scale, and then dried, usually has a dull-black appearance. If the work is to be polished, the black will be removed and the colour restored in the polishing process; but if it is to be plated, or if it is to be left with parts of iron showing, the work should be run through the bright dip. This will bring it out white, improving the appearance and tending to make it take on a white deposit if it is to be nickelled. This dip is composed of:—

Hydrofluoric acid, 24 oz. Nitric acid, 10 oz. Metallic zinc, 2 oz. Water, 2 gals.

Work that is to be dipped should be strung on copper wire, and swirled around in the solution for a few seconds, rinsed in cold and then very hot water, and dried in sawdust. Articles should not be allowed to stay in the dip any time, as they would be spoiled and the solution ruined.

Satin-finish Dips.—Brass work requiring a satin finish may be dipped for a few seconds into a mixture consisting of:—

(1) Hydrofluoric acid, 1 part; Water, 3 parts;

then dried and run through the bright dip (4) to give it a lustre. If not satined enough the operation may be repeated.

(2) Hydrofluoric acid, 2 parts; Nitric acid, 1 part; Muriatic acid, ½ part; Water, 5 parts. After which the work may be rinsed, dried, and run through the bright dip (4) if necessary.

(3) Hydrofluoric acid, 2 parts; Nitric acid, 1 part; Water, 10 parts.

The following is a *bright dip* for copper, brass, bronze, or German silver:—

(4) Hydrofluoric acid, 4 quarts; Nitric acid, 3 quarts; Common salt, small handful.

PROTECTION OF COPPER CASTINGS.

The best method for protecting copper castings from oxidation in air, resulting in a coating of verdigris, is for the casting to be done under hot water, with the metal at a very high temperature. This method, largely employed in Japan, forms a coating of red cuprous oxide, which has been known to give protection for upwards of thirty years.

Mechanical Treatment of Metals and Alloys.

Method of Treatment.	Details of Method to be avoided.	Consequences of Details of Method of Work.
Hot working . .	1. Excess 'reduction' or rate of 'reduction.'	Cracking of metal.
	2. Deficient 'reduction' or rate of 'reduction.'	Coarse, weak metal.
	3. Excess temperature at commencement.	Weak, brittle metal and formation of fissures therein.
	4. Deficient temperature at conclusion.	Internal strain and consequent hardening. Possible 'season cracking.'
	5. Retention of scale on metal during operations.	Rough and pitted surface and possible cracking.
Cold working . .	1. Excess 'reduction' or rate of 'reduction,' without annealing.	Surface cracking and hollow drawing. Strain-hardening.
	2. Deficient 'reduction' or rate of 'reduction.'	Insufficient hardening — where hardening is expected.
	3. Unequal 'reduction' . . .	'Season cracking' or cracking during annealing.

Heat Treatment of Metals.

Method of Treatment.	Details of Method to be avoided.	Consequences of Details of Method of Work.
Annealing . .	1. At too high a temperature .	'Burning' and 'over-heating' in steel and brass. Brittleness and sponginess generally, owing to abnormal grain size.
	2. At too low a temperature . .	Insufficient structure change.
	3. For too long a period — at correct temperature.	Diffusion and aggregation of micro-constituents of metal or alloy.
	4. Careless charging in or firing of furnace.	Sudden access of heat may lead to cracking of cold metal.
	5. In an injurious atmosphere or in contact with injurious substances.	Copper is injured by reducing gases, steel by oxidising gases. Water and oil have injurious effects in many cases.
Quenching . .	1. From too high a temperature .	Cracking, warping and brittleness.
	2. From too low a temperature .	The object of the operation is defeated.
	3. Unequal	Warping.
Tempering . .	1. At too high a temperature .	Removes the effects of quenching.
	2. At too low a temperature . .	Does not remove the effects of quenching sufficiently.
	3. Unequal	Lack of uniformity and consequent failure.

WELDING AND CUTTING.

(Contributed by D. Richardson, Wh. Exh., A.M.I.M.E., Capt. R.A.F.)

OXY-ACETYLENE WELDING.

The term 'autogenous welding,' which is a cumbersome and loose description for the process, has become synonymous with oxy-acetylene or gas welding, although its real meaning, 'self-producing,' does not fully apply. The term was chosen to describe a process in which two sections of metal are melted together by means of a blowpipe in contrast with the then existing methods, in which a joint was made by the addition of a different metal, as in brazing.

The easy control and intensity of the oxy-acetylene flame, the low cost of operation, the relatively inexpensive equipment required, the range of metals which can be welded, and the adequate supplies of carbide of calcium, oxygen, etc., available, are factors which have led to its many and varied applications.

The industrial development which has taken place can also be attributed to the increased efficiency of the welder and the efforts that have been made to reduce the art of welding to a more scientific basis. The uncertainty of the results, upon which opposition and criticism are usually based, can be traced to the following causes: (*a*) inefficiency of the welder; (*b*) use of defective or unsatisfactory apparatus; (*c*) use of defective or unsuitable filling materials; (*d*) lack of proper supervision and maintenance of the generating plant and equipment; (*e*) unsuitability of the material to be welded.

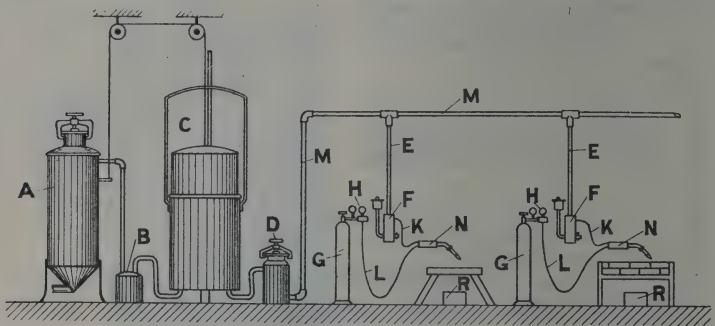
It is not difficult to eliminate these causes, and a well-trained welder using good apparatus, correct filling materials, etc., can produce welded joints on mild steel, cast iron, copper, brasses, bronzes, aluminium and aluminium alloys, lead, etc., with mechanical and physical properties approaching those of the base metal, and in which the strength and service of the joint are absolutely reliable.

Equipment.

The apparatus required for an oxy-acetylene installation depends upon several factors, such as (*a*) the class of work to be carried out; (*b*) whether a portable or stationary installation meets the case; (*c*) whether production or repair work, or both, are possible applications; (*d*) the facilities for installing equipment and for handling the work in prospect. In general, the apparatus and accessories will comprise a generator for generating the acetylene gas, which may be a fixed or portable plant—the most portable type of plant uses compressed or dissolved acetylene in portable safety cylinders instead of a generator; chemical and mechanical purifying apparatus; oxygen apparatus for the production of oxygen, or the use of oxygen in cylinders; oxygen regulators for lowering the pressure of the gas after it leaves the cylinder, to the pressure required for the blowpipe, and, in the case of dissolved acetylene, an acetylene regulator for the same purpose; hydraulic safety valve or other safety device; welding and cutting blowpipes of various capacities; accessories, such as flexible tubing, goggles, welding benches, blowpipe support, preheating devices, tools, jigs, fluxes and filling materials, carbon paste and blocks, fire protection, protective equipment, etc. etc.

Fig. 1 shows in diagrammatic form an elevation and plan of the general lay-out of an acetylene welding and cutting installation. The letters refer to the same details in both views.

The acetylene generator, shown at A, is usually automatic, that is, the generation of gas is controlled entirely by the gasholder regulating the water supply or the carbide supply; B is a condenser, washer, and water-seal; C is a gasholder, consisting of a tank to contain the water-seal and a bell to store the gas; D is a purifying chamber and filter. The main piping, M, is



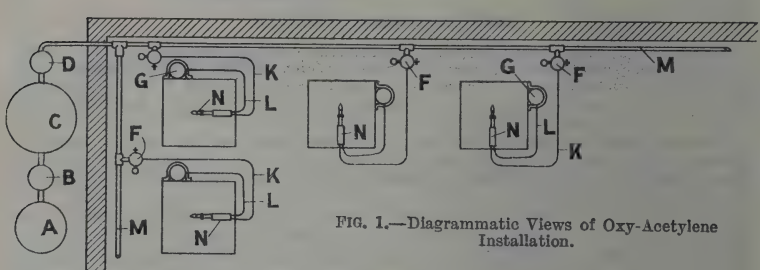


FIG. 1.—Diagrammatic Views of Oxy-Acetylene Installation.

connected to the purifying chamber and forms a complete circuit of the welding shop; branch pipes, E, are taken from the main for supplying acetylene to each welding station; F is the hydraulic safety valve or other safety device; a flexible tube, K, connects the hydraulic safety valve to the welding or cutting blowpipe, N; G is the oxygen cylinder, on to which is screwed

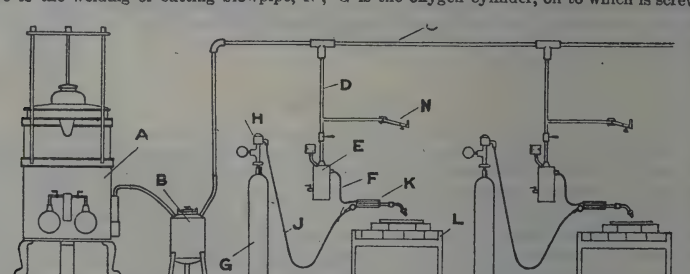

FIG. 2.—Diagrammatic View of Low-Pressure Oxy-Acetylene Installation.

the oxygen regulator H; a flexible tube, L, connects the oxygen supply to the blowpipe N; two common types of welding benches are shown.

In practice, and especially in small installations, the generator, condenser, washer, water-seal, and gasholder form a single piece of apparatus, as shown at A in fig. 2. The diagram

CHEAPER OXYGEN

from 12 *producing depots in the United Kingdom with a weekly output capacity of*

3,000,000 cu. ft.

But why cheaper?

¶ BECAUSE the actual cost of production is low. The LAL system of oxygen production is the most economical in operation.

¶ BECAUSE we are erecting oxygen supply depots all over the country—and so cutting transport costs.

¶ BECAUSE small plants (from 20,000 cu. ft. per week) are economical—and our service includes the erection of such privately owned plants.

¶ BECAUSE we specialise in the economical use of oxygen. We can show you how to use not only *cheaper oxygen*, but *less* of it.

A CARD to our headquarters at Queen's Park places you under no obligation and will bring you particulars of developments of the utmost importance to every user of oxygen.

Write To-day

shows at N a pilot light bracket attached to the branch tube D. An acetylene jet burner, consuming about 5 litres of acetylene per hour, screwed into the bracket, forms an efficient and economical method of lighting the blowpipe. The burner should be at least 18 inches from the hydraulic safety valve and not more than 6 ft. above floor level.

Fig. 3 shows the equipment for the high pressure system in which the acetylene is obtained from a cylinder of compressed gas. After passing through suitable acetylene and oxygen regulators the gases are conveyed to the blowpipe by means of flexible tubes.

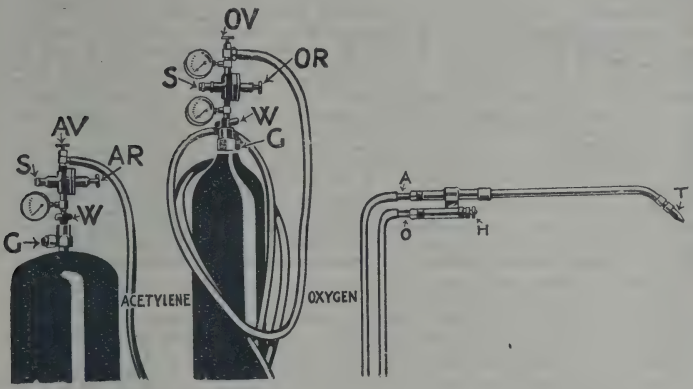

FIG. 3.—High Pressure or Dissolved Acetylene Installation.

OXYGEN SUPPLY.

The oxygen may be obtained in cylinders or may be produced on the premises. There are three methods of production, namely :—(1) chemical processes ; (2) the electrolytic process ; (3) the liquid-air process. The older chemical processes are practically obsolete as regards oxygen for welding and cutting. Modern chemical processes are represented by the Oxygenite, Oxylithe, and Epurite processes. The Oxygenite process consists in the liberation of oxygen in a closed vessel by the self-combustion of a powder called Oxygenite, which is composed chiefly of potassium perchlorate, to which are added small quantities of powdered carbon and fuller's earth. One pound of Oxygenite will set free a little more than 5 cubic feet of oxygen of 95-96 per cent. purity. In the Oxylithe process the chemical is brought into contact with water and the gas is liberated in a similar manner to the production of acetylene from calcium carbide. In the Epurite process the Epurite, which is a mixture of chloride of calcium, sulphate of iron, and sulphate of copper, diluted with water, produces oxygen. The main objections to chemical processes are the cost and impurity of the gas. The effect of impure oxygen in welding is to retard the welding operation, and thus increase the cost, and a tendency to produce blowholes. In cutting operations the purity of the oxygen is a most important factor, and tests have shown, for example, that with oxygen of 91 per cent. purity the cutting speed is halved when compared with oxygen of 98 per cent. purity. Simple and cheap apparatus is available for rapidly and accurately testing the purity of the gas.

The electrolytic and liquid-air processes may be used for producing oxygen on the premises. The gas can then be charged into cylinders or piped into the welding shop from large receivers into which it has been compressed, or it may be piped direct from the oxygen-producing plant. For information on 'Industrial Oxygen' reference should be made to a paper read by T. Campbell Finlayson on the subject before the Institution of Chemical Engineers, in June 1923, and the Report of the Oxygen Research Committee, Department of Scientific and Industrial Research, Sept. 1923.

Oxygen produced by the electrolytic or liquid air processes has a purity of the order 99 per cent. Unless the consumption is very large the first cost of an oxygen installation is too high, and the majority of users obtain the gas in cylinders from the manufacturers. The cylinders supplied by manufacturers for welding and cutting usually contain 100 cub. ft of gas at a pressure

of 1,800 lbs. per sq. in. The Gas Cylinders Research Committee of the Department of Scientific and Industrial Research have made a series of recommendations for ordinary commercial cylinders for the storage and transport ofgases, including oxygen, and are at present engaged on the standardisation of the fittings of gas cylinders.* The British Engineering Standards Association have also formed a committee with a view to standardising cylinder valves and fittings.

In handling oxygen cylinders care must be taken against leakages, and particular care must be exercised not to oil or grease any part of the oxygen apparatus or supply line. Dust and moisture should be expelled by opening the cylinder valve before the cylinder is put into use. Repairs to cylinder valves should not be attempted by the user, and full cylinders should be handled carefully. All oxygen cylinders are fitted with valves having right-hand connections. No attempt should be made to transfer oxygen from one cylinder to another by rigging up some form of communicating tube. In the majority of cases a separate cylinder is used for each welding station or blowpipe in use. In some cases a number of oxygen cylinders are manifolded together, the gas being supplied to the shops through a system of piping. Oxygen manifolds should be able to withstand a pressure of at least 3000 pounds per square inch and each cylinder connection should be equipped with a high-pressure shut-off valve. It is extremely advisable that the necessary manifolds be purchased from a responsible manufacturer or made to specification. A cylinder valve should never be opened suddenly when the oxygen regulator is attached. In the event of the oxygen supply being restricted owing to the freezing of moisture in the cylinder valve, hot water only should be used to put it right. Leakages can be discovered by the hissing noise produced by the escaping oxygen, by the use of soap-suds spread over likely places, or by closing the valves on the blowpipe, cylinder and regulator, and noting how long the pressure holds up on the gauges. Cylinders should be placed where they cannot be easily knocked over, and never near sources of heat. Spare cylinders should be safely and properly stored, care being taken not to store them near radiators, oil, grease, or combustible materials.

For estimating costs of welding, the following table will be found useful. The table gives the number of cubic feet of oxygen remaining in a 100 cub. ft. cylinder corresponding to various readings of the high-pressure gauge on the oxgyen regulator. The amount of oxygen indicated by the gauge reading is more or less approximate as it depends upon the temperature of the oxygen. For practical work the deviations can be ignored, and would not affect the usefulness of the table. In general, the volume of oxygen in a cylinder is nearly proportional to its pressure, and thus, in the absence of the table, the volume of gas remaining in a cylinder can be determined by observing the gauge. A pressure gauge which serves the double purpose of registering the pressure of the gas in the cylinder and indicating the amount which has been used on a welding or cutting operation, is now available.

Gauge Pressure in Atmospheres.	Cubic Feet of Oxygen in Cylinder.	Gauge Pressure in Atmospheres.	Cubic Feet of Oxygen in Cylinder.
10	8·3	70	58·4
20	16·7	80	66·7
30	25·0	90	75·0
40	33·4	100	83·4
50	41·7	110	91·7
60	50·0	120	100·0

Oxygen is supplied to the trade at prices which vary according to the size of the cylinder, quantity purchased, and other conditions. Cylinders are loaned, or may be purchased outright. Demurrage charges are made on hired cylinders when retained above a certain period. Oxygen cylinders are conveyed by the railway companies under strict regulations and conditions.

According to the British Oxygen Company, cylinders containing 100 cu. ft. of oxygen, and fitted with valves, should weigh not less than 104 lbs. full and 95 lbs. empty. If fitted with foot rings and valve-protecting caps, 13 lbs. should be added to the above weights. Cylinders with valves and containing 150 cu. ft. of oxygen should weigh not less than 144 lbs. full and 130 lbs. empty, and 15 lbs. should be added for foot rings and valve-protecting caps.

Acetylene Supply.

The acetylene may be obtained compressed in cylinders, when it is generally known as dissolved acetylene, or may be generated on the premises. The precautions in handling acetylene cylinders are much the same as for oxygen cylinders. The gas should not be drawn off at too

* *First Report of the Gas Cylinders Research Committee* (1921).

Dissolved Acetylene

'The Gas of Universal Application.'

DISSOLVED ACETYLENE has to-day attained a commanding position in the realm of industrial engineering. That success is due to its complete purity, high calorific value, safety, and the easily portable nature of the seamless steel cylinders in which it is stored. These qualities render it the most suitable medium for a very great variety of industrial purposes. Dissolved Acetylene cylinders and gas are daily supplied by the Company for:—

Welding and Metal Cutting; Brazing; Soldering; Leadburning; Paintburning; Lighting of Cars, Motor-Cycles and Commercial Vehicles; Flarelights; Harbour and Coast Lights; Buoys at Sea; Searchlights; Cinematograph Apparatus; Lighting of Trawlers and Motor Boats.

high a rate; in other words, the greater the demand the larger the cylinder. For heavy continuous work two or more cylinders should be manifolded together by means of special adaptors supplied by the company. For general work cylinders containing 100 to 250 cub. ft. of gas are advisable. All acetylene cylinders used for oxy-acetylene welding are provided with valves screwed with left-hand threads. Cylinders for welding and cutting can be hired or purchased.

	Etc., etc.				

Before the gas is compressed into cylinders it is first purified and dried by several processes, and then compressed in solid drawn seamless steel cylinders, filled with a patent porous filling substance, throughout the pores of which a film of acetone is held in suspension.

The acetylene and oxygen being under high pressure, a perfectly even mixture of both gases can be maintained in the blowpipe and the pressure varied according to requirements. The elimination of the injector device, necessary in low-pressure blowpipes, and the hydraulic safety valve are advantages claimed for dissolved acetylene or the High Pressure System, as it is called. Dissolved acetylene can be used with any type of oxy-acetylene blowpipe.

No demurrage charges for the use of cylinders are made on hired cylinders returned within thirty days of despatch, so that it is not necessary to purchase cylinders, although these can be supplied. Acetylene is supplied to users of purchased cylinders of 100 cub. ft. capacity and upwards at reduced prices.

The amount of acetylene in a cylinder cannot be determined, as in the case of oxygen, by the pressure gauge. The only accurate method of calculating the gas used from, or left in, a cylinder is by weighing before and after use. The empty and full weights are shown on a label fixed to each cylinder after charging. For calculating the volume of acetylene used the following are the equivalents:

1·1 ozs. of acetylene = 1 cub. ft. (approx.)
1 lb. „ „ = 14·5 „ „

By means of the acetylene generator acetylene is produced by the interaction of calcium carbide and water. There are three general types of acetylene generators which may be classed under the heads of water to carbide type, carbide to water type, and the dipping or displacement type. They can also be classified as low-pressure and pressure generators. Briefly, low-pressure generators deliver acetylene to the blowpipe at a pressure of about 8 ins. water pressure (0·036 lb. per sq. in.), whilst pressure generators deliver the gas up to a maximum fixed by regulations at 250 ins. water pressure (9 lbs. per sq. in.).

The design and layout of a generating plant must be such that the acetylene reaches the blowpipe in a good condition, in sufficient quantity and at sufficient pressure, otherwise the welds will be porous, brittle, and burnt. The acetylene generator should be of good and solid construction, and the gasholder capable of storing all gas generated under working conditions or after stoppage of work. There should be no signs of polymerisation or overheating of the gas even when working at the maximum delivery. The cross-section of tubes, pipes, and passages through valves should be such that the gas flows normally at the maximum delivery without loss

of pressure. The pressure of gas should be as high as possible, and at least equal to 6 ins. of water pressure in the case of small plants and 8 to 10 ins. in larger plants. The pressure should remain practically constant during working and not vary more than $\frac{1}{2}$ in. water pressure. The charging and cleaning of the plant should not result in any appreciable waste of gas, and be made without introducing sufficient air to interfere with the working of the blowpipe. The generator should comply with the Regulations of the British Acetylene and Welding Association. The size of carbide suitable for the type of generator should be used. For commercial purposes carbide is broken and packed in the following sizes 80/120, 50/80, 25/50, 15/25, 7/15, 4/7, 2/4, and 1/2 millimetres. The figures refer to the approximate mean thickness of a lump in millimetres. The 50/80 size is in great demand for welding and cutting generators. The choice of carbide-to-water, water-to-carbide, etc., generating plants depends on several factors, such as location, class of work, etc.

The Carbic system of generation is based upon the use of a carbic cake, which consists of specially prepared and treated carbide compressed into cylindrical cakes. It is claimed that the process renders every particle of carbide impervious to moisture, so that generation can only take place while water is in actual contact with the cake. Freedom from danger in handling, and from after-generation, convenience in handling, elimination of waste and purity of gas are factors which have led to the success of this system.

Overloading of the plant is a common cause of defective welds. In carbide-to-water generators an allowance of not more than one cubic foot of acetylene per hour for each pound of carbide in the rated charge is recommended. In the case of water-to-carbide generators the maximum rate of gas consumption should be half this value. In well-designed generators the yield of acetylene gas from the generator will be 85 to 90 per cent. of the carbide yield. Practically, for every 10 lbs. of carbide used in the generator a yield of 40 cub. ft. of gas at the blowpipe can be assumed. The proper care, cleaning, charging, and maintenance of generators is of first importance if reliable welds are required. Leakages of acetylene should be traced by means of soap-suds and never with naked lights.

The acetylene generating plant should be installed in a well-ventilated shed or building, or in a lean-to having no direct communication with a workshop or adjacent building, and no unauthorised person should be allowed to enter the building. Where artificial light is required in a generator house or near a generator, electric incandescent bulbs, encased in outer gas-tight globes, should be used. A conspicuous notice prohibiting lights or smoking should be exhibited on the outside of the generator house. Generatcrs should be cleaned and charged in daylight. Electric switches, fuses, etc., should be placed outside a generator house, or they should be so constructed that risks due to sparking or fusing are avoided. To comply with existing regulations, a licence under the Petroleum Acts (fee 5*s.* per annum) must be obtained from the local authority for the storage of carbide, where a stock of more than 28 lbs. is kept. A raised platform in the generator house should be provided for the storage of carbide. Drums containing carbide should not be placed in the welding shop or near a flame. Care must be exercised in opening drums to avoid striking sparks ; a proper drum opener should be provided for this purpose.

Purification of Acetylene.

The chief impurities found in acetylene gas are (*a*) those which affect the quality of the weld, such as sulphur, phosphorus, silicon, finely subdivided lime ; and (*b*) those which affect the cost of the weld, such as hydrogen and hydrogen compounds, nitrogen and nitrogen compounds, and water vapour. An efficient chemical purifier must be provided capable of removing sulphur and phosphorus compounds, the acetylene must pass through an efficient water-scrubber to remove or partially remove the impurities soluble in water and, finally, the gas should be filtered to remove solid impurities not eliminated by washing or chemical purification. A first-class purifying material will generally remove chemical impurities, moisture, and lime dust which are a common cause of defective welds.

Purification of the gas must be efficient, and the care and maintenance of the purifying chamber is very important. The cross-sectional area of the purifier should be ample, and the depth of purifying material should not exceed that specified by the makers, otherwise loss of pressure and overheating of the gas will take place. The quality of the gas can be simply and quickly tested by the use of a white absorbent paper, saturated with a 10 per cent. solution of silver nitrate and exposed to the gas. Should the paper turn black after a few seconds' exposure, the gas is unsuitable for welding purposes.

Among the best-known purifying materials are Heratol, Catalysol, Klenzol, and Suder. The three last are distinguished by their regenerative properties—that is, they recover their activity by simple exposure to the air, and thus can be used over and over again. In purifying acetylene the cost should be based on the volume of gas purified and not on the first cost of the material.

Preservation of Acetylene Apparatus.

The question of preventing the corrosion or deterioration of the material used in the manufacture of acetylene generators, purifying vessels, and other parts of the generating plant is important in view of the fact that according to the efficiency of the coating the life of the plant may be a question of months or years.

There are five cases to be considered, namely : (*a*) preservation of the external parts of the apparatus ; (*b*) preservation of the immersed parts ; (*c*) preservation of parts in contact with

OXYGEN *and* DISSOLVED ACETYLENE

supplied in our own or customers' cylinders from any of our Works. Accessories for use with these gases also supplied, including Blowpipes, Regulators, Rubber Tubing, &c., &c. Cylinders and Cylinder Valves.

moist and impure gas; (*d*) preservation of the interior of purifying vessels; and (*e*) preservation of carbide containers. With regard to (*a*), good ironwork paints give good results when applied well to properly prepared surfaces. At least two coats should be applied. If the apparatus is exposed avoid paints used for woodwork, plaster, etc. For (*b*) it is necessary to use a waterproof paint which will resist the prolonged action of water. The best results are obtained when the base consists of tar and graphite. For (*c*) the paints used for immersed parts of acetylene apparatus give the best results, but the work must be done with great care. For (*d*) the majority of industrial preservative paints give satisfactory results, except those containing a zinc or similar base. Several coats are necessary, and great care is required in applying the coats on to well-prepared surfaces. For (*e*) tests have shown that no paint or coating will satisfactorily resist the action of the lime residue at the temperatures usually present, and that the lime residue appears to have a preservative action on the parts in which it is in contact. It is therefore unnecessary to protect these parts.

Oxygen and Acetylene Regulators.

Regulators in common use to reduce the pressure of gases are of the diaphragm type, and may be roughly divided into two classes—first, where the pressure of the gas closes the inlet, and, second, where the inlet is closed by a spring. They are designed to automatically deliver gas to the blowpipe at any uniform pressure to which the regulator is set. They should be designed for working over a wide range of pressures, and should be sensitive even at low pressures. Oxygen regulators are usually equipped with two gauges, a high-pressure gauge, which shows the pressure of gas in the cylinder, and a low-pressure gauge. For successful welding the regulator should be provided with a low-pressure gauge, giving the pressure at which the gas is delivered to the blowpipe. The range of the low pressure gauge should not be too great, and a maximum reading of 75 lbs. per square inch will be sufficient for the majority of welding and cutting operations. Regulators must be kept in good order, otherwise defective welds are inevitable. Regulators intended for use when welding should not be used when cutting unless the work is within the range of the regulator. It is dangerous to use oil, grease, or any organic material for lubrication. If it becomes necessary to lubricate the pressure-regulating screw, or to repack a needle valve, make use of a little glycerine. The pressure-adjusting screw should always be released after ceasing work and before changing from one cylinder to another. Creeping regulators or regulators with leaky valve seats should be overhauled, because they are likely to become dangerous and uneconomical. The gradual increase of pressure when the blowpipe is shut off indicates a creeping regulator. Regulator gauges should never be tested with an oil-testing pump.

Acetylene regulators are usually painted red and have a left-hand screw thread corresponding to that on the standard valves of acetylene cylinders. Regulators for oxygen are painted black and have a right-hand screw thread. Any possible confusion is obviated by this distinction.

Cylinder valves should be opened very slowly so that pressure does not come on to the gauges or diaphragm suddenly. The proper working of regulators largely depends upon the care given them. They should not be left in places where dirt or dust may get into the interior and be deposited on the seat or inlet nozzle, and they should never be repaired by inexperienced workmen.

Hydraulic Safety Valves.

These are indispensable in low-pressure and medium-pressure installations, i.e. where the acetylene is generated on the premises. Their function is to provide a water-seal and to prevent explosive mixtures entering the acetylene piping or generating plant. The valve should be chosen so that the maximum supply of gas is obtained without burning the metal. Safety devices based on mechanical principles, such as valves, etc., may more or less prevent the return of the flame, but are not infallible in preventing explosive mixtures forming in the generating plant.

Hydraulic safety valves should be charged and examined daily, and should be installed so as to facilitate filling to the proper level. In general, the valve should be charged with water whilst the acetylene tap admitting gas to the valve is open. No safety valve should have more than one outlet to which a blowpipe can be connected.

Pressure relief valves or safety valves used on pressure generators should be tested periodically; they do not replace the hydraulic safety valve, which is still required in a modified form.

Piping and Flexible Tubes.

The acetylene piping should be large enough to avoid loss of pressure. The size of piping should be dependent upon its length and the maximum supply of gas required. All piping should, when possible and convenient, be run overhead. When piping has to be run underground it should be placed in properly ventilated trenches. Piping and connections should be installed by workmen experienced in the installation of acetylene apparatus. Piping should be so arranged that any moisture will drain back to the generator, and where low points cannot be avoided these must be drained through drip cups closed with screw caps or plugs. No pet cocks should be used. A main gas cock should be arranged where it can be conveniently reached and near the point of

entrance, so as to allow for shutting off the gas supply from any workshop. Gas cocks should be provided on the branch tube leading to the hydraulic valve so that a valve may be removed without discharging the line. All cocks, valves, unions, and joints should be full bore, and the installation should be thoroughly tested when the system is completed. It should not show a loss of pressure exceeding two inches of mercury within twelve hours when subjected to a pressure equal to a column of fifteen inches of mercury. Acetylene piping should be painted a distinctive colour. Galvanised iron pipe with threaded connections should be used for piping acetylene. The pipes should be of uniform diameter, and bends, the number of which should be as small as possible, should be used in preference to square elbows.

The following table will serve as a guide in installing acetylene piping for welding purposes.

Acetylene Main Piping.

Approximate Diameters of Service Piping. For working pressure of 6 in. to 10 in. water column.

Consumption of Acetylene per hour.	Length of Pipe.	Internal Diam. of Piping.
Cubic feet.	Feet.	Inches.
15	100	$\frac{1}{2}$
40	100	$\frac{3}{4}$
80	100	1
140	100	$1\frac{1}{4}$
225	100	$1\frac{1}{2}$
400	200	2
1000	200	3
2500	200	4

Ordinary black steel piping may be used for low-pressure oxygen and extra heavy steel pipe for high-pressure lines. No oil or grease must be used for the connections; litharge and glycerine should be used. The diameter of oxygen piping will depend on the length of the lines. A $\frac{3}{4}$-inch pipe is suitable for supplying twenty welding stations provided the length of the line is not more than 300 feet and the maximum consumption is not more than 500 cu. ft. per hour.

The flexible tubes conveying the gases to the blowpipe should not be too long, too flexible, or too rigid. Armoured or wired hose is not necessary or recommended for ordinary welding and cutting operations. Three-ply tubing with a core of pure rubber is satisfactory for ordinary work, and for welding and cutting in confined spaces fire-resisting hose should be used. Avoid greasing the ends of the tube to facilitate fixing to the blowpipe or other connectors; use water. Tube clips should be used in preference to wire, etc., for securing the tube firmly to the connectors.

Flexible tubing should be examined regularly, and defective tubing should never be used Avoid tangling or kinking the hose, long lengths—about 10 ft. lengths are suitable,—dragging the hose along the floor, and exposing it where it is likely to get damaged. Special care should be taken to avoid the interchange of the oxygen and acetylene tubes when connecting up to the blowpipe. Both acetylene and oxygen tubing should be blown through occasionally, so that d irt and dust will not get carried into the blowpipe.

Welding Blowpipes.

Welding blowpipes are classified in relation to the pressure of the acetylene. Low-pressure blowpipes are those fitted with an injector to aspirate the acetylene, which is supplied from a generator under a pressure of 6 to 12 inches of water. Medium-pressure blowpipes, sometimes called positive pressure, use acetylene generated from a pressure generator at a pressure up to 15 lbs. per sq. in. An injector or partial injector forms part of the blowpipe. Recent developments have led to the introduction of blowpipes which use the acetylene at a pressure little different from that used with positive pressure blowpipes, but with the important difference that the oxygen pressure is considerably reduced, being, in fact, less than the acetylene pressure. High-pressure blowpipes use the acetylene supplied from acetylene cylinders, and are designed to mix acetylene and oxygen in equal volumes. No injector is required, and a change of nozzle with a corresponding adjustment of pressures is all that is required when changing over from welding one thickness of material to another.

In the low-pressure system efficient mixing of the gases in the blowpipe is very necessary. To obtain this, well-designed blowpipes carefully adjusted to the oxygen pressure recommended by the maker are essential. A typical low-pressure blowpipe working on the injector principle is shown in fig. 4.

The size or power of blowpipe which should be used depends upon the thickness to be welded. By power is meant the amount of acetylene consumed per hour. Too small a power produces the defects of adhesion, inclusion of oxide, overheating, and burning of the welds. Too large a power produces a molten bath which is much too large, holes, and adhesion in the lower part of the weld.

The figure denoting the power of blowpipe is usually supplied by the maker, and is sometimes marked on the blowpipe. In welding materials other than wrought iron and steel the power of blowpipe to be used is dependent upon the material, its dimensions, and whether preheating has been adopted. As a general rule the power of blowpipe for a given thickness of material is greater, as in melting, for example, cast iron, copper, or aluminuim, more heat is required to melt a given weight of the metal, and, in addition, the high temperature part of the flame is held farther from the molten metal.

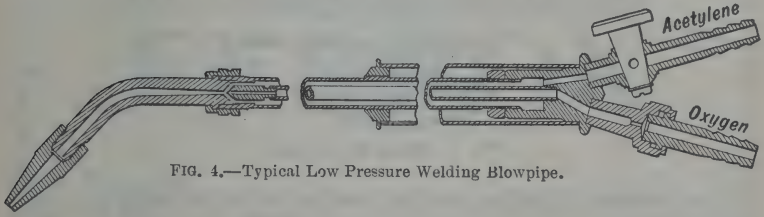

FIG. 4.—Typical Low Pressure Welding Blowpipe.

All blowpipes should be carefully handled and treated as precision tools. The procedure to be followed in lighting and extinguishing the blowpipe varies with the design and type of blowpipe. The manufacturer's instructions should be closely followed. Lighting devices are convenient and safer than matches. A blowpipe should never be put down, unless a blowpipe stand is provided, until the gases are turned off, and should never be hung from regulators or other equipment. Carefully avoid the use of grease or oil, and never dismantle a blowpipe with a view to overhauling, as this may lead to irregular working after assembling. In the event of obstruction of the nozzle, a soft brass wire should be used for cleaning. Dust in the interior of the blowpipe can be removed by blowing oxygen through from the nozzle end. In the case of back-firing due to overheating the tip should be cooled in water, taking care to close the acetylene valve and to leave the oxygen valve slightly open.

Back-firing, which is a common cause of defective and expensive welds, may be due to one of the following causes :—

(*a*) Faulty design and manipulation of the blowpipe.

(*b*) Enlarging the nozzle orifice when removing obstructions.

(*c*) Working in confined spaces or with an accumulation of slag on the nozzle.

(*d*) Necessity for overhauling and internal cleaning.

(*e*) Restricted and fluctuation in the acetylene supply due to bad lay-out, exhausted purifier, etc.

(*f*) Defective hydraulic safety valves leading to air and moisture being carried with the gas.

(*g*) Defective oxygen regulators.

(*h*) Presence of solid matter in the gas either from the acetylene generator or inferior flexible tubing.

OXY-ACETYLENE FLAME CHARACTERISTICS.

The combustion of acetylene in oxygen produces a flame which consists of two parts—an inner cone, incandescent, clear, and well defined ; and a non-luminous outer envelope which may be transparent or more or less opaque according to the purity of the acetylene. The exact character of the flame will depend on the proportion of the oxygen and acetylene as they emerge from the nozzle. The oxygen and acetylene should mix in approximately equal proportions. Varying proportions of the gases produce three characteristic types of flames

commonly known as carbonising, neutral or normal, and oxidising. These are shown in fig. 5. It is important that at all times the flame should be neutral—that is, there should be no excess of oxygen or acetylene. Defective welds are produced with carbonising and oxidising flames. It is particularly important that there should be no excess of oxygen, which not only tends to produce weak welds, but also to blow the metal forward and produce adhesion. Regulation of

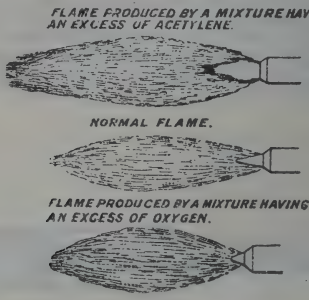

FIG 5.—Flame Characteristics.

the flame during important welding operations is essential, as very few blowpipes maintain a neutral flame under welding conditions, and further, the operator has a tendency to adjust the flame oxidising.

It is necessary to emphasise that the white cone of the flame should never be brought into contact with the molten metal, and that its distance from the molten metal depends upon the kind of metal being welded and its thickness.

GOGGLES AND PROTECTIVE EQUIPMENT.

For welding with acetylene it is necessary to protect the eyes with goggles fitted with suitable coloured glasses. There are a great many different kinds of special safety glasses on the market and many combinations of ordinary coloured glass are in common use. The eyes must be protected from injurious rays, the heat and glare from the work and from particles of hot metal that fly up from the weld. To obtain the clearest definition or visibility with the least amount of glare, the selection of the colour tint in safety glasses should properly be decided by an expert; the depth of the tint may be determined best by the operator himself, owing to the individual difference which will permit one man to see clearly through a glass that would be too dark for another man. Amber, dark-amber, or dark-amber-green glasses are the most efficient protection. Glasses showing blue or violet tints should be avoided, except in certain combinations where they are used to obscure other colours.

Welders employed on heavy work should be supplied with fireproof gauntlets and aprons, as a protection against radiated heat, and where welding is being performed in the interior of some structure or confined space all the outer clothing should be fireproof.

Filling Materials.

The necessity for employing the best materials for every welding operation cannot be too strongly emphasised. It is only by using the most suitable filling-in wires, rods, and fluxes, specially manufactured and controlled for each particular metal or alloy, that the most satisfactory work can be done.

Thin material may frequently be welded by bringing the edges into contact and melting them together, but generally a filling material or 'welding rod' is melted into the groove or crack. Filling materials must not only be of the correct chemical requirements so as to replace loss in the molten zone, to counteract the tendency of the metal to oxidise, to assist in making the molten metal flow readily, or to break down oxides when formed, but they should also act satisfactorily under the blowpipe.

The choice of the right size of welding wire or rod is important, and melting of both should take place in the molten bath and not in the flame. The following table gives the sizes of wire for 'forward' welding iron and steel. In the case of other metals the figures hold good, except for very thin material, when a size of not less than $\frac{1}{16}$ in. should be used.

FERROX COMPANY LIMITED

Manufacturers of Welding
Wire, Rods and Fluxes for

OXY-ACETYLENE WELDING

FERROX

□ □ □

FERROX for Iron, Steel, Wrought Iron and Malleable Cast Iron—requires no flux.

is the finest and most scientifically prepared Welding Wire produced and is used all over the World.

is particularly suitable for Building up operations by the Bare Wire Arc Process.

FROXITE A special composite rod for Hard Welds—particularly suitable for Railway and Tramway repairs.

SIFROX A Cast Iron Rod with high Silicon content—giving a weld which is easily machined.

SIFLUX Specially prepared Flux for use with Cast Iron Rods.

Aluminium, Brass, Copper, Phosphor-Bronze Rods and Rods for Nickel Steel, Chrome Steel and Manganese Steel Welding.
Fluxes for use with the same.

Use FERROX materials and you will use THE BEST.

F. 2597

SIZES OF WELDING WIRE FOR IRON AND STEEL ('FORWARD' WELDING).

Thickness of Material.	Size of Welding Rod.		
	S.W.G.	Decimal equivalent.	Nearest $\frac{1}{64}$.
Gauge 20 to 19 to 18	16	0·064	4
$\frac{1}{16}$ inch	15	0·072	5
$\frac{1}{8}$ "	12	0·104	7
$\frac{3}{16}$ "	9	0·144	9
$\frac{1}{4}$ "	6	0·192	12
$\frac{5}{16}$ "	5	0·212	14
$\frac{3}{8}$ "	3	0·252	16
$\frac{7}{16}$ " to $\frac{1}{2}$ "	2	0·276	18
$\frac{9}{16}$ " to $\frac{5}{8}$ "	0	0·324	21

The following table also gives the sizes of wire for 'backward' welding; it should be pointed out that this method of welding is more reliable and economical than 'forward' welding, and is rapidly displacing the latter in the welding of iron and steel.

Thickness of Material.	Size of Welding Wire.		
	S.W.G.	Decimal Equivalent.	Nearest $\frac{1}{64}$
Gauge 20 to $\frac{1}{8}$ in.	14	0·081	5
$\frac{3}{16}$ in.	11	0·116	8
$\frac{1}{4}$ to $\frac{5}{16}$ in.	8	0·160	10
$\frac{3}{8}$ in.	6	0·192	12
$\frac{7}{16}$ to $\frac{3}{4}$ in.	4	0·232	15

Fluxes.

It is not always possible to include deoxidisers and special elements in the welding rod itself. By using a combination of chemicals in the form of a powder, liquid, or paste, known as a flux, the difficulties of producing sound and reliable welds are frequently overcome. A flux is used for the purpose of cleaning the parts to be welded, for eliminating and preventing the formation of oxide, for replacing elements burnt out by the flame, and, when melted, protecting the surface of the molten metal from the action of the flame and preventing the formation of blowholes. The mantle of a well-regulated and well-manipulated flame protects, in a measure, the molten metal from oxidation. A flux is necessary in welding steel (except in cases where the steel welding wire contains deoxidizing materials, as, for example, Ferrox), cast iron, copper, aluminium, etc.; for successful welding the proper flux should be used, and as the welding rod and flux are important factors in welding they should only be obtained from reliable manufacturers.

Preparation of the Work.

One of the first principles of sound welding is securing complete fusion and perfect union of the filling material and the edges of the parts to be welded. To ensure this, good preparation is necessary, which includes, as a rule, the cleaning of the edges and the welding wire, the bevelling or chamfering of the edges, the adjustment and maintenance of the parts in position, and allowance for expansion and contraction effects. In general, the preparation of the parts varies according to the thickness and nature of the metal and upon the organisation and equipment of the workshop.

Cleaning the parts to be welded and the welding wire or rod is essential. Bevelling is necessary for materials $\frac{1}{8}$ in. and above in thickness. Bevelling ensures good penetration, increase in

ductility and strength, economy, and reduces the overheating effects. The angle of the bevel depends upon the thickness of material and whether 'forward' or 'backward' welding is practised. All metals from $\frac{1}{8}$ inch up to $\frac{3}{8}$ inch, and in some cases $\frac{1}{2}$ inch, should be bevelled from one side only. Where possible, pieces exceeding $\frac{1}{4}$ inch should be bevelled from both sides. In forward welding the V formed by the two bevelled plates should be about 90°. In backward welding for material up to $\frac{1}{4}$ inch an angle of about 45°, and above $\frac{1}{4}$ inch an angle of 60°, can be used. The bevel should extend to the bottom of the plate, and thorough penetration and complete fusion should be obtained. In repair work preparation of the work is a very important feature and will save considerable time and keep the cost of welding low. Should it be necessary to re-weld a joint previously welded, it is essential that the weld metal be entirely removed and on old work the same instruction applies, and corroded metal must be removed. In the case of aluminium repairs, for example, good judgment, as shown by the preparation, means success, and bad judgment a ruined casting.

Expansion and Contraction.

It is impossible to produce satisfactory work unless expansion and contraction effects are properly allowed for. Warpage and internal strains, followed by failure, are the common result of welders failing to master this subject. The methods commonly employed are, in the case of thin sheets, tacking; in the case of heavier material and castings, setting the plates so as to form an angle, heating the entire work, partial heating, heating restraining members, breaking a member so that expansion and contraction can take place freely, bending or springing the material, etc.

If the expansion can take place in all directions, it will give the welder no trouble, but he should operate so as to leave practically no residual stresses. If, however, the welding takes place at a point that is confined by various parts or by the particular construction of a piece, it is then necessary to give it due consideration.

The resultant effect of contraction must be considered equally with that of expansion, as failures, cracks, etc., can often be traced to neglect to allow for this property.

Preheating.

This may be partial or total, depending upon the work in hand, and is mainly employed with a view to (*a*) allowing for expansion and contraction, (*b*) decreasing the cost of welding, and (*c*) producing a more homogeneous joint. Preheating is usually carried out with the welding blowpipe, oil or gas burners, charcoal, or other suitable fuel. Where fuels such as charcoal are used for preheating, the combustion gases should, where possible, be carried away. In any case ventilation should be provided to avoid the harmful effects of the gases produced by combustion. The method used should be governed by the particular work in hand.

No general rules can be given for preheating temperatures, as the degree of heat necessary will, of course, depend upon the size and shape of the object to be welded. As a general rule, however, cast iron should be preheated to a dull red heat for small and simple castings, and to a blood-red heat for large or complex castings; aluminium and its alloys should be preheated very carefully, as too high a temperature will lead to the collapse of the article being welded.

Preheating machines burning paraffin and giving a flame of high calorific value, smokeless and transparent, have been introduced and give satisfactory results where portability and a powerful flame are required.

After Treatment of Welds.

Improvement in the structure of welds with a consequent increase in strength and ductility is the result of proper after treatment of welds. Thermal or mechanical treatment, or both, carried out in a correct manner is always beneficial, except in the case of defective welds.

Strength of Welds.

With proper equipment and suitable filling materials, the strength of a weld will depend mainly upon the care and skill of the operator. A good operator should be able to obtain welds 95 per cent. the strength of the original material; for the average welder 85 per cent. should be taken as the lower limit of strength.

Steel Welding.

The welding of wrought iron and mild steel is apparently simple; in reality it is somewhat difficult to produce strong and reliable welds. Oxidation is the most serious defect, and this must be reduced to a minimum. Welding wires containing a small percentage of vanadium or nickel have recently been introduced, with highly satisfactory results. To produce the minimum

of oxidation the blowpipe must be well designed and handled efficiently and the parts to be welded must be thoroughly cleaned. The use of a flux in the form of a powder has, up to the present, not proved satisfactory. It has been found that deoxidising material in the form of a liquid gives excellent results. The product known as 'Suder' is specially prepared for use with a welding wire which does not contain deoxidising elements. At the high temperature of the flame it slags the oxide, keeps the surfaces clean, and prevents the inclusion of oxide. The weld can be carried out rapidly, thus reducing overheating effects. The liquid is applied by means of a brush to the edges of the plates and the welding wire previous to welding. Expansion and contraction must receive proper consideration. The welding wire should be a material low in phosphorus and sulphur, and free from oxide. The use of ordinary iron or mild steel is unsatisfactory, and welding wire, such as Rylax, 'Suder' or 'Ferrox, made especially for the oxy-acetylene process, should be insisted upon. It will be found that economy is on the side of the scientific but more costly product.

The following specification for a welding wire for iron and mild steel is of interest and represents the American Welding Society's Specification for the welding wire to be used for oxy-acetylene welding mild steel, structural work, plates, bars, low carbon steel forgings and castings. The surface of the wire is to be smooth, of uniform homogeneous structure, free from irregularities in surface hardness, segregation, oxides, pipe, seams, etc. Diameter shall not vary more than + 3 per cent. of the diameter specified. The chemical composition to be within the following limits :—

Carbon	not more than	0·06	per cent.
Silicon	,,	0·08	,,
Manganese	,,	0·15	,,
Sulphur	,,	0·04	,,
Phosphorus	,,	0·04	,,

The surface shall be smooth and free from scale, rust, oil, or grease. In the hands of an experienced welder the wire shall demonstrate good weldability, and shall flow smoothly and evenly without any unusual characteristics.

For welding mild steel and to produce a weld of greater strength but of lower ductility than that obtained with ordinary welding wire, the wire should contain 0·15 to 0·25 per cent. of carbon, 3·25 to 3·75 per cent. of nickel and 0·5 to 0·8 per cent. of manganese.

A simple test to indicate the fitness of welding wire is made by laying the wire flat on a clean surface and applying a good neutral oxy-acetylene flame to the wire in such a manner as to heat it up for a distance of about 3 or 4 ins., playing the flame backwards and forwards until the wire is red and then slowly melting the wire, moving the flame so that the wire only melts halfway through its diameter. If the flame is withdrawn as soon as the metal begins to melt, the impurities can readily be seen being thrown off in the form of sparks, or a boiling action in the case of inferior metal ; and in some cases the metal will not flow together, but 'runs away.' In the case of clean metal free from impurities the wire will melt and flow evenly without any disturbing action.

The following table is of use as a guide in ordering welding wire :—

Size, inches	$\frac{1}{16}$	$\frac{3}{32}$	$\frac{1}{8}$	$\frac{5}{32}$	$\frac{3}{16}$	$\frac{1}{4}$	$\frac{5}{16}$	$\frac{3}{8}$
Lbs. per 100 ft. .	1·04	2·3	4·1	6·5	9·3	16·7	26	37·5
Ft. per 100 lbs. .	9,615	4,273	2,403	1,537	1,067	600	383	266

The flame must be carefully regulated and held so that the tip of the white cone is about $\frac{1}{8}$ in from the surface of the molten metal.

A good practical rule in welding steel is that the hourly consumption of acetylene should be 4¼ to 5¼ cub. ft. (120 to 160 litres) for every $\frac{1}{16}$ in. in thickness.

A very useful table can be made up from these figures, in which the approximate bore of the nozzle orifice is included.

POWER OF BLOWPIPE FOR IRON AND STEEL.

Thickness of Material in inches.	Consumption of Acetylene per Hour. In Litres.	In Cub. Feet.	Bore of Nozzle in $\frac{1}{64}$ inch.
22 gauge	60–80	2¼–2¾	2
$\frac{1}{16}$	120–160	4¼–5¾	3
$\frac{1}{8}$	240–320	8½–11	3 full
$\frac{3}{16}$	360–480	12¾–16½	4
$\frac{1}{4}$	480–640	17–22	5
$\frac{5}{8}$	720–960	25½–33	6
$\frac{1}{2}$	960–1280	34–44	7
$\frac{5}{8}$	1200–1600	42½–55	8

The blowpipe must be given a motion which will cause the flame to describe a series of overlapping circles in the case of light and medium sheets, and oscillated in a series of semicircles in the case of heavy sections. This is known as 'forward' welding. A variation of these movements has been introduced which gives more economical and better welds. The welding iron, in this case, follows the flame instead of preceding it, and the flame is directed towards the starting point instead of towards the finishing point. The blowpipe is given a slight gyratory motion, whilst the welding rod is given a more or less elliptical or longitudinal motion. This method of welding is known as 'backward' welding. Subsequent thermal treatment, which may consist of annealing or normalising, according to the particular requirements, will improve the structure of steel welds and materially increase the strength and toughness of the weld. Hammering may be resorted to with good effect, provided the hammering is not too vigorous or done at too low a temperature.

The following table gives the speed at which the welding of mild steel plates can be done under average conditions:

Thickness of Plate in Inches.	Speed of Welding.	
	Feet per Hour.	Feet per Hour for Average Day's Work.
$\frac{3}{64}$	30 to 33	23 to 26
$\frac{5}{64}$	20 „ 21	16 „ 20
$\frac{1}{8}$	15 „ 16	13
$\frac{5}{32}$	13 „ 15	10
$\frac{13}{64}$	10 „ 12	9
$\frac{7}{32}$	9 „ 10	$7\frac{1}{2}$
$\frac{9}{32}$	8 „ 9	$6\frac{1}{2}$
$\frac{21}{64}$	7 „ $7\frac{1}{2}$	6
$\frac{23}{64}$	$5\frac{1}{2}$ „ 6	5
$\frac{13}{32}$	$4\frac{1}{2}$ „ $4\frac{1}{2}$	$3\frac{1}{4}$
$\frac{15}{32}$	$3\frac{1}{4}$ „ $3\frac{1}{2}$	$2\frac{1}{2}$ to 3
$\frac{19}{32}$	2 „ $2\frac{1}{2}$	$1\frac{1}{2}$ „ 2

Owing to metallurgical changes that take place when melting medium and high-carbon steel with the blowpipe, the welds obtained are invariably unsatisfactory. It is possible to get fair results on medium steels, but a flux, rapid welding, and thermal after treatment, which requires skill to properly carry out, are necessary.

The data at hand shows that for welding medium carbon steel, welding wires having a carbon content ranging from 0·06 to 0·60 per cent. are of no particular value.

For welding high carbon steel and worn surfaces where great resistance to abrasive wear is desired and where machining is not necessary, a welding wire containing 0·06 to 0·75 per cent. of carbon and 0·60 to 0·90 per cent. of manganese is desirable.

Alloy steels, such as chrome and manganese steel, are weldable, provided the percentage of carbon does not bring them into the range of medium and hard steels, which is frequently the case. The welding wire should be of the same character as the steel, and a flux must be used. In the case of nickel steel it is necessary to use a flux which will form a varnish over the molten metal and prevent the absorption of the gases from the flame of the blowpipe. The welding of alloy steels where great strength is required is in the experimental stage, as there are many important problems, such as preheating, heat treatment, etc., to be considered.

Cast-Iron Welding.

The two principal defects in cast-iron welding are the production of hard spots and blowholes in the weld and subsequent cracks or fractures in the weld or adjacent metal. The oxide formed must be removed or destroyed by the use of a flux. The welding rod must be of good material and specially made for cast iron welding. One great trouble with cast-iron rods in general is that the quality is by no means uniform. This is especially true with the cheaper and uncontrolled products. Rods made from ordinary cast iron produce blowholes and hard spots. Special rods containing titanium, producing sound, soft, and reliable welds, are obtainable. Expansion and contraction should be considered as of great importance. Preheating should be used to some extent in all cast-iron welding. It is advisable to weld in position after preheating. The welder is protected by making use of asbestos sheet or simply plate. Specially designed blowpipes of considerable length are available for this class of work, and two or three welding rods are welded together. The parts must be thoroughly cleaned, and in the case of cracks their extension must be prevented by drilling holes a short distance from the ends in the direction the crack would follow. The weld should be arranged horizontally, and where this cannot be arranged carbon blocks should be used to prevent the metal flowing away. Carbon products, in the form of blocks, powder, or paste, play an important part in modern welding operations. They are far superior to fire-

clay or fire-bricks, which are liable to melt under the blowpipe and invariably cause blowholes. Carbon compound, in powder form, which can be made into a plastic mass with water, is valuable for making moulds, dams, etc., and for lining up repairs and holding parts in position. To protect machined surfaces during preheating operations, they should be coated with flaked graphite and oil. This can be made into a paste and painted on, or the surfaces can be oiled and the graphite dusted on. The graphite must be coarse, as fine flake is not satisfactory. The flame must be held so that the tip of the white cone is between $\frac{1}{4}$ and $\frac{3}{4}$ in. from the molten metal, the distance depending on the thickness of the metal. The after-treatment consists in annealing or allowing the metal to cool very slowly. In well-executed welds on cast iron the quality of the weld is generally superior to that of the metal of which the casting is made. The grain is finer and the welded zone is sound, homogeneous, and can be easily worked.

Certain cast irons of great strength and in which the carbon is in the combined state are practically unweldable. Cast iron which has been submitted to the heat of a fire for a considerable time is frequently unweldable. The metal in both cases melts under the blowpipe in a distinctly different manner from ordinary cast iron, and the welder should have no difficulty in recognising that the blowpipe should not be applied to make a joint.

Malleable Cast Iron.

It is difficult to produce satisfactory joints on malleable cast iron by welding. The welds are hard, brittle, and porous. The best results are obtained by brazing with the oxy-acetylene blowpipe, using the same methods of preparation as for cast iron, and using manganese bronze as a filling material. The two pieces to be joined are brought to a point just below fusion, great care being taken that they do not become fused. When the edges are at a right temperature, the rod of manganese bronze is fused into the groove with the aid of a good flux.

The introduction of acetylene for brazing purposes provides a fuel which has the highest known flame temperature and high calorific value. By using dissolved acetylene with a special brazing blowpipe no air-bellows or oxygen is necessary, as the blowpipe is atmospheric and a clean and relatively small flame is obtained.

Aluminium Welding.

Sheet aluminium welding can be handled in very much the same way as steel as regards preparation and allowance for expansion and contraction. The principal difficulty lies in the formation of the oxide, which must be dealt with by an energetic and reliable flux. The filling material is pure aluminium wire; before starting to weld, the wire and parts to be welded must be thoroughly cleaned by scraping. A delicate touch and considerable practice are necessary, especially on thin material. Material under 22 gauge is best welded after flanging the edges. The flanged edges should practically have no radius, so as to leave the minimum of space between the underside of the sheets. The depth of the flange should be about two and a half times the thickness of the sheet. The white cone of the flame should be level with the surface of the plates and the blowpipe held so that the flame is inclined to the horizontal at about thirty-five degrees. If the methods are correct the upper and lower surfaces of the weld appear identical. The power of the blowpipe to be used is not in direct ratio to the thickness of the metal as in steel welding. For example, on 16 to 19 gauge material a blowpipe consuming 2 cubic feet of acetylene per hour would be satisfactory, whilst for material $\frac{1}{8}$ in. thick 10 cubic feet is required, and for $\frac{1}{4}$ in. material, 40 cubic feet, per hour. The flame must be carefully regulated, and the tip of the white cone should be from $\frac{1}{4}$ to $\frac{3}{4}$ in. from the molten metal. After welding, the welds should be thoroughly washed with warm water and, where possible, internal strains should be removed by annealing. The structure and strength of the metal in the welded zone are improved by hammering when cold.

Pure aluminium is not usually employed for castings subject to stress. In order to raise the tensile strength and increase the hardness varying percentages of zinc, copper, or nickel are added. There is an endless variety of aluminium alloys, but from a welding point of view they fall into two classes, viz., those containing zinc as their principal hardening medium and those containing copper. The material expands greatly and is very weak at high temperatures, consequently contraction strains are likely to produce cracks and distortion unless the work is properly handled. In welding castings—crank cases, for example—it is often necessary to preheat them either completely or partially. The preheating must be done carefully, otherwise the casting may collapse. For supporting the casting evenly and lining up, carbon putty is useful. For missing parts, and where the welder is not well skilled in this class of work, it is advisable to back up with sheet copper or galvanised iron. In rigging up jobs for repairs, care must be taken that expansion and contraction effects are not interfered with. The parts should be carefully cleaned and free from oil and grease. A good grade of filling material of average composition is necessary; pure aluminium wire should not be used. The acetylene should be pure and the blowpipe should give a soft, non-oxidising flame. Two methods of welding are adopted, one known as the flux and the other as the puddle method. In the former a flux is used in the ordinary way and in the latter no flux is used, a steel rod and paddle being used to remove or break down the oxide and to smooth the weld respectively. All traces of flux must be washed off. The casting should be reheated slightly to remove any local strains and then allowed to cool very slowly. For finishing off a single cut-file or a 'dreadnought' file is most suitable.

The welding of the well-known aluminium alloy known as 'Duralumin,' which contains copper, manganese, magnesium, etc., is satisfactory or not according to the mechanical properties required in the joint. The alloy has important properties which are reduced, and in some cases almost eliminated, by welding operations. The metal should not be welded when the joints are subject to bending action, shocks, or when the full properties of the metal are desired.

Copper Welding.

Copper may be welded, but only satisfactorily where the operator is familiar with the technique. Many failures can be attributed to the metal being in an unsatisfactory condition for welding. Where possible, a sample strip two or three inches long should be tested by making a weld and applying the bending test. It is necessary to clean and bevel the edges and to support the underside of welds by means of a mandrel consisting of an iron tube on which is wound or fixed asbestos, which must be perfectly free from moisture. Owing to its lack of strength when hot, the tacking of copper welds should be done carefully. For the same reason welds should not be started at the edges of the sheets, but at a point about one-third the length of the seam. The power of the flame should be practically the same as that used for welding steel of the same thickness. The flame must be carefully regulated. The melting should not be too rapid or too slow. Without a correct welding rod, which contains a small quantity of phosphorus, it is impossible to satisfactorily weld copper. A flux is useful. Preheating to avoid adhesion is necessary. The tip of the white cone should be about $\frac{1}{4}$ in. from the surface of the molten metal. The welds should be hammered at a dull-red heat to improve their ductility and strength, and afterwards annealed.

Brass and Bronze Welding.

These are only welded indifferently without the correct welding wire or rods. The filling material for brasses and bronzes should be almost of the same composition as the metal to be welded, which, in the case of brass, should contain a little aluminium, and in the case of bronze a little phosphorus and traces of aluminium. Bronze filling materials are cast. Fluxes should be used in both cases, and the power of the flame is less than that used for the same thickness of copper—that is, distinctly less than for steel plates of the same thickness. The regulation of the flame is very important, a slightly oxidising flame will give a surface free from wrinkles. The position of the flame is the same as for copper. The after-treatment of the welds consists in annealing at definite temperatures.

Lead Welding.

The oxy-acetylene blowpipe is rapidly supplanting the older methods of welding lead, or 'lead burning,' as it is generally called. It has proved superior in convenience, quality of joints, and economy. A small type of blowpipe is required, consuming from $\frac{1}{2}$ to 6 cub. ft. per hour. When it is necessary to fill up a hole or to build up any part of a lead object, the work is facilitated by using a mould or a backing of steel plate. When welding patches in repair work avoid rectangular patches on vertical faces, which makes two edges of the patch horizontal. The patch should be made lozenge shape, so that the welds are done on the incline. The welding wire or rod should be of the same metal as the sheet.

Nickel Welding.

Nickel when melted has the property of readily absorbing gases, especially oxygen. Various methods have been tried to protect the molten metal from the gases of the blowpipe and to prevent the absorption of gases. The welds obtained are very porous, and it is extremely difficult to obtain satisfactory welds. A method which has given fair results consists in placing the two parts to be welded on a heated anvil and then heating the parts to a white heat with the blowpipe, afterwards carefully hammering the parts together.

Machines for Welding.

Acetylene welding machines for the manufacture of tubes have been in use for many years. The development of automatic welding machines for the manufacture of tanks, etc., is more recent. For repetition work machines have been designed which accomplish the work in less time with comparatively unskilled men. The machines consist of two parts, (*a*) holding device for the work, and (*b*) apparatus for carrying the blowpipes, with or without motion, over the seam.

Recent developments in welding machines have been mainly in the direction of the use of multi-jet blowpipes. In order to obtain speed it was recognised that more than a single jet of flame should be employed, and from two jets in tandem it has become customary to employ a large number of jets extending for a considerable distance along the line of the weld. The defects of this method have been overcome by distributing the heat on both sides of the centre line of the seam. The welded section produced in this way is wider, stronger, and more certain to penetrate than is the case with the narrow weld made by a central line of flame.

Training Welders.

An oxy-acetylene welder has been defined as a person who has the requisite manipulative skill and technical knowledge successfully to operate welding and cutting apparatus, and, at

Two of the Reasons why the CARBIC Portable Welder and Cutter will serve you well

1. It delivers its acetylene to the blowpipe at constant pressure. This ensures an even temperature at the weld, and freedom from oxidation and carbonisation troubles.

2. Because the supply of acetylene is derived from Carbic Cake there is no waste.

And there are other reasons. A Booklet is waiting to convince you that the Carbic System of Welding and Cutting is more economical and altogether more satisfactory than any other method you now use.

Full particulars of the Carbic 1,000 c.p. Flare and the smaller Carbic Hand Lamps will also be sent you.

Write To-day.

the same time, has skill in the operation of hand tools used in the preparation and finishing of the work in connection with welding, and also has a reasonable amount of ingenuity. He must also have a knowledge of accuracy commensurate with the type of work to be welded. Naturally, a trade in which so much depends on the personal equation has drawn attention to the need of training men to produce sound work. No doubt the best method is that which expounds principles followed by practice under expert supervision. Welding skill grows rapidly under a well-worked-out system of exercises which aim at developing skill in making typical welds on various metals. Testing the welds is also an important requisite of a training course. Classes for training welders are held in the principal centres, and manufacturing concerns who train their workmen must follow methods depending upon the size of shop and class of work.

A common error is to attempt work, especially repair work, in a shop where the tools and apparatus for successful all-round welding are not provided, or to endeavour to repair jobs which are beyond the capacity of the welder. It is much more economical, in such cases, to hand over work of this character to firms specialising in general repairs who have the necessary equipment for carrying out and testing the work, and welders who are not mere blowpipe operators.

Testing Welds.

The importance of testing welds has, in recent years, become very great. It is well known that the quality of a weld cannot be assumed from the general appearance, finish, etc. At the present time the usual methods of testing include tensile and impact tests on specimens welded under identical conditions, microscopic examination of specimens, bending and hammering tests, and X-ray examination. In the latter the actual welds can be examined, and flaws, blowholes, and other defects discovered. Recent investigations indicate that electrical and magnetic tests for the non-destructive examination of welds will soon find commercial application.

The American Bureau of Welding have drawn up Standards for Testing Welds which are intended primarily to serve as a standard uniform basis for testing and comparing sample welds as distinguished from welds on structures. The testing of the latter must necessarily be by non-destructive methods, which would therefore be, in general, quite different from those employed in examining sample welds made for the purpose of testing a welder's proficiency, comparing welding wires, or comparing welding methods. For the shop standard a bending test is recommended ; for the commercial standard, a bending and tensile test on approved lines.

Miscellaneous Applications.

There are numerous applications of the oxy-acetylene process not included in the term welding, but which have a direct or indirect connection with it and are worth consideration. The oxy-acetylene flame, for example, is a convenient and simple method of applying local heat for numerous workshop operations, such as forging, straightening, riveting, expanding for shrinkage fits, heat-treatments, etc.

Brazing operations are more efficiently carried out with the oxy-acetylene flame. Case-hardening and surface hardening can also be efficiently and economically done with the flame.

OXY-ACETYLENE CUTTING.

Wrought iron, steel, and steel castings can be cut with the ordinary cutting blowpipe, and with a special cutting blowpipe, or the ordinary cutting blowpipe operated in a special manner, cast iron can be cut.

The cutting blowpipe usually consists of a compound jet made up of one or more heating flames with a pure oxygen jet in the centre. The purity of the oxygen is of much greater importance when used for cutting than when used for welding. As the purity decreases the oxygen consumption and time increases, and the speed of cutting decreases as the following figures, which represent tests on steel plates 5 feet long by 1 inch thick, show :—

No. of Test.	Purity of Gas, per cent.	Time in Seconds.	Oxygen Consumption in cubic feet.	Remarks on Cuts.
1	99·7	280	8·0	Very smooth and clean.
2	99·4	291	8·8	Smooth.
3	99·1	315	9·8	Satisfactory.
4	98·0	334	11·3	Good but rough.
5	96·0	365	13·2	Not smooth.
6	95·0	412	15·4	Very irregular.
7	90·0	644	20·0	Rough, surface bad.
8	87·0	675	23·0	Very rough, surface bad.
9	85·0	696	25·8	Very rough, unsatisfactory.
10	82·5	—	28·4	Very rough & not through.

A spot of the metal is first heated to a bright red heat with the heating flame, and then the oxygen jet is turned on. It has been proved that only partial combustion takes place, the phenomenon of cutting being really a disintegration by the current of gases from the blowpipes. The oxy-hydrogen flame is often used for cutting in place of acetylene. Material up to 36 ins. has been cut. The same acteylene equipment is used for cutting as for welding. For heavy cuts special oxygen regulators are used. There are two kinds of cutting blowpipes, known as the 'central' and 'following jet' types. Mechanical contrivances have been devised for special forms and shapes and for heavy cutting. One type of machine, known as the Godfrey Universal, uses as its cutting instrument the oxy-hydrogen or the oxy-acetylene blowpipe. It has the full range of movements found on a machine tool intended for universal use. The degree of accuracy is such that accurate gear teeth can be cut, and 1, 2, or any desired number of thousandths can be left for finishing.

The following table is an abstract from the manufacturers' table of cutting data.

TABLE OF APPROXIMATE METAL-CUTTING RESULTS.

(*British Oxygen Co., Ltd.*)

Thickness of Plate.	Oxygen pressure at Regulator Outlet.	Consumption of Oxygen per hour.	Foot run of Metal cut per hour.	Oxygen consumed per foot run of cut.

14	125	900	12	75
17	130	1,350	12	112

Blowpipes can be obtained for cutting steel under water. Under-water cutting is based on the fact that the water must be forced away from the heating flame and cutting jet. Up to recently compressed air has been used for this purpose, but the latest type of under-water cutting blowpipe makes use of the products of combustion. The cooling action of the water necessitates using a heating flame five to seven times as powerful as that used for cutting the same thickness of material in the ordinary way. With an efficient arrangement an ordinary hand-cutter can be adapted for cutting under water. In salvage work steel plates have been cut at a depth of 40 ft. Various devices for lighting the flame under water when it becomes extinguished have been successfully introduced.

The cutting blowpipe for cast iron is of the same character as that used for cutting steel, except that in some cases an ordinary iron tube fitted with several wires in the interior is used for the cutting operation. An ordinary iron tube, of approximately $\frac{3}{16}$ in. internal diameter and an exterior diameter of $\frac{3}{8}$ in., containing three wires of 12 gauge, gives the most regular and satisfactory results for the demolition of castings, etc. The pressure of oxygen varies, according to the thickness to be cut, between 70 and 150 pounds per square inch. The process of cutting cast iron consists of piercing a series of holes along the desired line of cut; the cutting operation is much more rapid than appears at first sight.

TABLE OF CAST IRON CUTTING RESULTS.

ELECTRIC WELDING.

Electric welding processes can be placed in two distinct groups, one producing heat by the resistance of the metal being welded to the passage of the current, the other using the heat of the electric arc. They are known as Resistance Welding and Arc Welding, respectively. These two main groups have formed the basis for many processes of welding. The differences rest entirely on methods and special applications. The subdivisions are as follows :—

Arc Welding.
(1) Carbon or graphite electrode.
(2) Metallic electrode.
  (*a*) Bare electrode.
  (*b*) Coated electrode.
  (*c*) Covered electrode.
(3) Electric blowpipe.

Resistance Welding.
(1) Butt welding.
  (*a*) Flash welding.
  (*b*) Upset welding.
  (*c*) Automatic butt or contact flash.
(2) Mash welding.
(3) Seam welding.
  (*a*) Butt seam welding.
  (*b*) Lap seam welding.
  (*c*) Bridge seam welding.
(4) Percussive welding.
(5) Spot welding.
  (*a*) Lap spot welding.
  (*b*) Bridge welding.
  (*c*) Button welding.
  (*d*) Disc depression welding.
  (*e*) Point welding.
  (*f*) Multiple point welding.
  (*g*) Multiple electrode welding.
  (*h*) Ridge welding.
  (*i*) T spot welding.
  (*j*) Duplex spot welding.

The many systems of welding which have developed from these main groups are generally associated with the inventor's name or company exploiting the process, such as :—

Benardos System.	Thomson System.	Quasi-Arc Process.	Ferro-Arc Process.
Slavianoff System.	Premier Electric System.	Daysohms System.	A.C. Welding System.
Kjellberg System.	Alloy Welding Processes.	Cyc-arc Process.	Fluxode System.
Zerener System.			

ARC WELDING.

Commercial efficiency of arc welding processes is estimated by the relation that the quality of the work bears to the cost. The principal factors which decide the quality of the work are: (*a*) electrodes; (*b*) current (D.C. or A.C.); (*c*) welding equipment; and (*d*) efficiency of the welder. In assessing the cost the principal factors are: (*a*) capital expenditure; (*b*) depreciation and maintenance charges; (*c*) wages; (*d*) cost of electrodes; and (*e*) cost of electrical energy. The speed of welding enters into the question of cost provided increased speed is not obtained at the expense of welding efficiency.

Carbon Arc Welding.

The characteristic principle of this process, commonly known as the Benardos process, is that an electric arc is held between the metals to be joined, which forms one electrode of the circuit, and a carbon rod or pencil manipulated by the welder which forms the other electrode. By placing the carbon electrode in contact with the metal, thus closing the circuit, and instantly withdrawing it again, an electric arc is formed between the two electrodes and, owing to the high temperature of the arc, the metal is melted. Steel up to $\frac{3}{32}$ in. is satisfactorily melted together without using a filling material, but for greater thicknesses a 'melt bar' is melted into place by the heat of the arc. Automatic machines for repetition work on thin materials and equipped with carbon electrodes are in use. Experience has shown that the metal to be welded should be the positive electrode, and the carbon the negative electrode. If this order is reversed, a shorter arc is obtained and particles of carbon can enter the molten metal and cause brittleness.

The current used is direct, the voltage being from 60 to 90, and the amperes vary from 250 to 600, depending upon the thickness of the metal.

The use of graphite electrodes in place of hard carbon electrodes is increasing as the merits of the graphite electrode are more widely known. The chief advantages are: (*a*) breakage in handling and in operation is appreciably reduced; (*b*) breakage and cracking due to sudden changes of temperature is eliminated; (*c*) less carbon is carried into the weld; (*d*) the arc is much steadier; (*e*) the life is from two to three times as long as for an amorphous carbon electrode of the same diameter; (*f*) electrical conductivity is four times that of the carbon electrode of the same cross-section, consequently the heating caused by resistance is negligible and much higher current densities can be carried. Considerable development is being made in the art of carbon arc welding where graphite electrodes are used, and an automatic carbon arc welding machine has been placed on the market. The single or double graphite arc has proved useful in the welding of non-ferrous metals.

Metallic Arc Welding.

The use of metallic electrodes for arc welding has proved more satisfactory than the use of carbon or graphite electrodes, which necessitate feeding the new metal into the arc by means

of a rod or wire. A very wide variety of metal electrodes are used and can be classified as follows: (*a*) bare wire; (*b*) coated electrodes manufactured by dipping in, or brushing with, a liquid; (*c*) coated electrodes, which are wrapped with a refractory material or otherwise encased in a much heavier covering than that used for coatings. They can also be classified as: (*a*) heavy slag depositing electrodes; (*b*) light slag depositing electrodes; (*c*) flux-coated electrodes which deposit no slag, and (*d*) bare wire. Generally speaking, there is a sphere of utility for each type, and provided care is exercised in their selection, a weld of maximum efficiency should be obtained.

Bare Electrode.

The Slavianoff System, using a bare metal electrode, has not been developed in this country to any extent. There is considerable discussion as to the efficiency of bare electrodes, and although it may be possible to successfully weld mild steel with such electrodes, where toughness is desirable or necessary, or for the welding of steel alloys, a coated or covered electrode will give better and, in many cases, the only successful results. The decision of Lloyd's in approving the use of covered electrodes has not caused the adherents of the bare-metal electrode to abandon their position. The bare electrode imposes a minimum thermal load, but requires the presence in the equipment of a high stabilising factor. The following specification has been recommended for bare iron and steel electrodes for welding mild steel, steel forgings and castings, plates, bars, etc.:

Carbon	0·06	per cent. maximum.
Manganese	0·15	" "
Phosphorus	0·04	" "
Sulphur	0·04	" "
Silicon	0·08	" "

In the hands of an experienced welder electrodes should demonstrate good weldability in 'flat' and 'overhead' positions, and should pass through the arc smoothly and evenly without any unusual characteristics.

The data at hand shows that bare steel electrodes having a carbon content between 0·18 and 0·85 are of no particular value.

Coated and Covered Electrodes.

The use of coated and covered electrodes aims at improving the metal in the weld, permitting the use of alloy steels, non-ferrous metals, etc., as electrodes and facilitating electrode manipulation and the use of alternating current. Covered electrodes may be placed in two general classes, the first class being the electrode which has a heavy covering of scientifically prepared material containing a deoxidizer. The second class of covered electrode is of the type which has a very thin coating on the wire and aims at obtaining the same results as the heavy covered electrodes without the disadvantage of manipulating the heavy coating of slag deposited during the welding operation. It is possible to obtain as many as twenty different types of flux-covered electrodes, each specially designed for depositing a particular material. As a result of recent research work, electrodes are now available for the purpose of welding and depositing non-ferrous metals.

Kjellberg System.

The effect of refractory coverings on the metal electrode was first discovered by Kjellberg. In the Kjellberg process, controlled by the *Anglo-Swedish Electric Welding Co., Ltd.*, the steel rod is covered with a coating or sleeve of normally non-conducting materials—that is to say, conductors of the second class—the function of the cover being, amongst other things, to direct the metal where it is required, to protect the fused metal from oxidation, and to make up the loss in the arc, of certain constituents of the iron or steel forming the object.

In carrying out the process the covered rod is held in a clip or holder connected to a continuous current supply, and forms the positive pole, the object forming the negative, though in some cases the poles are reversed.

The covering is removed from the end of the rod to enable the current to pass and an arc is struck between the rod and the object. As soon as the arc is struck a portion of the metal of the object, having an area approximately equal to the section of the rod, fuses together with metal from the end of the rod, and at the same time the covering, which is of a friable nature, partly fuses and breaks away at the same rate as the metal of the rod is deposited. In this way metal can be gradually deposited on an object until a sufficient quantity has been obtained for the purpose required. From time to time the deposited metal is hammered so as to consolidate it in exactly the same way as a weld made in the fire.

A further advantage of the covering on the rod is that the tensile strength of the weld can be varied within certain limits to suit the purpose required. For example, by this process a tensile strength of from 20 to 35 tons per sq. in. can be obtained. It is possible also to obtain various degrees of hardness merely by altering the composition of the covering.

Quasi-Arc System.

In this process, controlled by the *Quasi-Arc Co., Ltd.*, the electric arc is superseded by a quasi (or partial) arc, which is brought about by a slag covering around the wire of the ordinary metal electrode. The electrode known as the Quasi-Arc Electrode, according to British Patent

Specifications 11079–12 and 13538–14, consists of a steel wire core with an aluminium wire running beside it and covered with a wrapping of *blue* asbestos suitably treated.

In making a weld or reinforcing a worn surface the electrode is held in an insulated holder connected by flexible leads to the positive pole of an electric generator and an arc is struck between the electrode and the work carrying the negative connection ; this arc is immediately destroyed and a quasi-arc formed and maintained, owing to the blue asbestos covering passing into the molten state and acting as a secondary conductor maintaining electrical connection between the work and the metallic core of the electrode.

The welding operation is continued by holding the point of the electrode just under the surface of the molten slag, and the quasi-arc is thus maintained and metal is deposited on the work continuously and with regularity.

Blue asbestos, being a ferrous silicate and an acid flux, can, in the molten condition, combine with and remove oxide or scale from work, so that it is not necessary to clean the latter in order to obtain a good junction between the electrode metal and the work. The molten steel and adjacent work, from the time of fusion until in the solid condition, is covered with this acid flux, so that oxygen from the atmosphere is prevented from entering the weld and oxidising the steel and forming blow holes. This is considerably helped by the presence of the aluminium wire, which readily takes up oxygen. The slag formed on the surface of the weld is of great advantage, as it covers the weld uniformly and allows the steel to cool much more slowly, thus adding to its mechanical strength, and when cool is easily removed.

The heat of the arc is localised to the weld, and the junction between the work and the welding metal is complete and free from oxide inclusions and shows a gradual diffusion of carbon from the work into the metal.

The following tables give the comparative strength of riveted and quasi-arc welded joints :—

TABLE SHOWING COMPARATIVE TENSILE TESTS OF QUASI-ARC ELECTRICALLY WELDED JOINTS, AGAINST RIVETED JOINTS.

QUASI-ARC WELDED LAP JOINTS.

The quasi-arc process has been authorised by the British and Foreign Admiralties, Lloyd's Register of Shipping, the British Corporation for the Survey and Registry of Shipping, Det Norske Veritas, and Nederlandsche Scheepvaart-Inspectie Bureau, for use in the more important parts in ship construction.

Quasi-Arc electrodes were exclusively employed in the construction of the all-welded motor ship 'Fullagar' of 400 gross tonnage, and she has passed successfully three annual surveys by Lloyd's Register.

Among later achievements of the Quasi-Arc process is its application to a completely welded 3,000,000 cubic feet gasholder, 200 ft. in diameter, 100 ft. high, with three lifts. Since this gasholder was satisfactorily completed, others have been constructed by the same method, together with the whole of the necessary framework. In addition, gasworks plant, including retort houses, condensers, gas mains, etc., has also been Quasi-Arc welded.

The Quasi-Arc process is used in all the royal dockyards and by the principal railway and tramway companies, collieries, mines, engineering firms and shipyards in Great Britain and abroad.

Note on Corrosion, in relation to Quasi-Arc Welding.

In view of the importance which the subject of corrosion bears to that of welding, the following notes on this matter may be added:—

Fundamentally, corrosion is electrolytic in character, and depends on the difference in potential of contiguous areas.

Commercial iron and steel contain areas which in the presence of an electrolyte (which may be merely atmospheric moisture) are capable of forming voltaic circuits, the necessary conditions being afforded by the presence of small particles of impurities or by local conditions of strain in the metal itself. These impurities or strains give rise to areas of higher electrolytic potential, and form electro-positive points which are first attacked by the corroding agent. Thus, in a caulked joint, corrosion will commence at the caulking, and similarly a riveted joint will be attacked round the rivet head, owing to the local strains in the metal at these points.

In a welded joint, if the metal at the weld be less pure than the surrounding metal, the weld will be first attacked. Similarly, if the added metal be not homogeneous, local differences in potential in the weld itself will cause corrosion at the weld.

A microscopic examination of the metal deposited by the Quasi-Arc process shows it to be of great purity, and the usual laboratory tests show it to be always electro-negative to the surrounding metal. Hence it follows that a Quasi-Arc weld will have a high factor of resistance to corrosive influences.

Alloy Welding Processes System.

The 'A.W.P.' electrodes are flux-covered electrodes, in which the coating and the metal core have been specially selected to give the best results as regards tensile strength and ductility, combined with ease of application and reliable and uniform results. The electrodes are coated by special machinery designed to suit the flux and deposit a perfectly even, concentric, and correctly proportioned amount of flux around the rod.

The slag produced is of such low specific gravity and high viscosity that it does not in any way impede the flow of the metal, or mix with the molten metal and get trapped when cooling. In making a second run the slag need not be removed except by slight brushing to remove dust and loose pieces. The electrodes produce a stable, even, and quiet arc, and the metal is evenly deposited and easily controlled. Special alloy electrodes can be supplied to successfully weld any particular specification of steel, and for welding and depositing non-ferrous metals.

Arc welding plant to meet all conditions, portable and self-contained, and for use on alternating and direct current supplies, have been designed from efficiency and economy points of view. The 'A.W.P.' electrodes can be used on alternating or direct current. If the operator is on direct current from a separate generator the voltage should be adjusted by the shunt regulator to as near 60 volts as possible. If welding with alternating current a non-inductive grid resistance should not be used in the circuit to adjust the current. An adjustable choking coil, which provides the same variation in current in addition to steadying the arc and saving power, should be obtained.

Premier System.

The standard electrodes manufactured by the Premier Electric Welding Co., Ltd., are composed of a steel alloy of carefully controlled composition and coated externally with a thin layer of non-metallic substances. The volatile coating ensures that the molten metal is protected to a considerable extent from atmospheric oxygenation and nitrogenation, and the composition of the electrode itself ensures that a sound weld with good mechanical properties is produced.

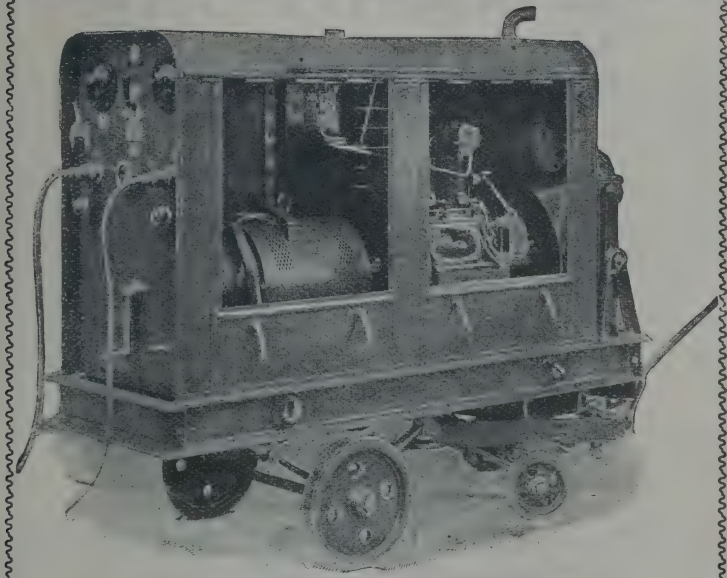
Five types of electrodes are manufactured as standard products, viz. general service electrodes, cast iron, manganese steel, medium carbon, and high carbon electrodes; in addition to which special electrodes can be supplied where necessary.

The Premier system of arc welding aims at distributing the current at the required welding voltage without any mechanical control whatsoever. This is obtained by the use of a dynamo of a special type connected with the arc through a special reactance coil in the main circuit. This coil absorbs no appreciable energy, but effectively damps out any sudden rise in current, and at the same time helps momentarily to build up the current when any sudden reduction takes place.

ELECTRIC ARC WELDING

APPROVED BY

Lloyd's Register of Shipping, the British Corporation for the Survey and Registry of Shipping, and Bureau Veritas.



COMPLETE PLANTS SUPPLIED.

A.W.P. Electrodes give equally good results on either Direct or Alternating Current. Made in 16 Types, to suit all classes of Iron and Steel, including special Electrodes for Cast Iron, Stainless Steel, Copper and Brass.

AN IMPORTANT 1925 ADVANCE IN MULTIPLE OPERATOR ELECTRIC ARC WELDING PLANT

This new equipment has the following advantages:

1. 70 Volts for Arc Striking.
2. 35 Volts for Welding.
3. No interference between Welders.
4. No bad spots in the weld from insufficient arc striking voltage.
5. Only about 7½h.p. per Welder.
6. Large wasteful resistances done away with.
7. 50% more efficient than any other Multiple Arc Plant with 70 Volts for Arc Striking.
8. Can be used for Carbon Arc Welding or Cutting if required.

In fact it is practically THE DROOPING CHARACTERISTIC MACHINE FOR TWO-TEN OPERATORS AT LAST

For particulars apply

THE PREMIER ELECTRIC WELDING CO. LTD.

NOBEL

ABBEY WOOD S.E.2

Proprietors: Nobel Industries Limited

The company have recently placed on the market an entirely new plant of the multiple operator type which does away with the large and wasteful series resistances which are a part of almost every other standard equipment. It is claimed that as a result of the new design, the power consumption of the equipment is approximately 50 per cent. of all other multiple plants of British manufacture, and the method of operation is briefly as follows :—

The main welding generator develops current at 35 volts and is direct coupled to a small arc striking generator which gives a small current at an additional 35 volts. By means of the special Brookhirst Contactor Gear which is fitted to this plant, a combined voltage of 70 is at all times available, for either or both welders, for the purpose of striking the arc, and, as soon as an arc is struck, the contactor gear previously referred to automatically cuts out the arc striker, and welding proceeds on the main generator.

It will thus be seen that the new plant is effective for welding at 35 volts; thus effecting considerable economy in running costs. Approximately 7½ h.p. is required per welder, this figure being slightly more in case of plants for a small number of operators and slightly less in case of plants employing six or more operators. First-class welding results are obtained without causing the slightest difficulty in striking and maintaining the arc and without any trace of interference between welders.

Ferro-Arc System.

The Ferro-Arc system employs electrodes with a full coating of flux. The core metal of Ferro-Arc electrodes is of the highest quality and made to an exact specification for arc welding. The principal component of the flux is powdered blue asbestos fibre specially treated and combined with other substances which control the melting point of the asbestos and enhance its power of dissolving oxides of iron and other impurities. Blue asbestos is peculiarly suitable for use as a flux, and it is doubtful whether any other material or combination can give such successful results in arc welding.

Ferro-Arc flux fuses evenly and level with the melting of the metal core, and when molten is fluid, free, and mobile, entirely covering and protecting the deposited metal. The flux has definite deoxidising properties which, together with its powerful solvent action for oxides, ensures the deposition of clean metal free from impurities. The scavenging action of flux removes scale and rust from the surfaces to be welded, and so results in perfect fusion and interpenetration of weld and parent metals.

In addition to the standard blue asbestos coated electrodes, the company manufacture a second grade of electrode, which is also fully coated and sold under the name of ' Ferrodes.' Remarkably good results are obtained with these electrodes, the outstanding features of which are smoothness of working, penetration of the metal, and neatness of finish.

Both the standard electrodes and Ferrodes may be used with either direct or alternating current on any standard arc welding set. The arc is smooth, steady, and easy to maintain, while current consumption is reduced to a miniumm. Vertical and overhead welding may be readily accomplished with either.

The Ferro-Arc cast-iron electrode has been specially designed to deposit a true cast iron in the weld and to eliminate the difficulties hitherto encountered when welding cast iron by older methods. Other alloy electrodes are supplied as desired.

Daysohms' System.

This system is designed to work on ordinary alternating current supply circuits, and is portable or stationary as desired. One of the advantages claimed is the special adaptability of the device for the safe welding of very thin metal; strips of mild steel, No. 20 S.W.G., have been welded in angle form at the rate of 1 ft. in 2 min., the current being 27 amperes at 65 volts on open circuit with a power factor of 0·45. The supply current is transformed to the necessary voltage and then passes through a choking coil. This has a straight core, with pivoted keeper which can swing, the speed of its movement being controlled by a dashpot. Limits can be set to the movement on each side by means of camform stops. With passage of current the keeper of course tends to be attracted towards the core, and the nearer it approaches, the lower the flow of the current, owing to the increased choking effect. The limit of the approach is set by the adjustable cam, and in this way any welding current within the limits can be obtained. The other cam, which controls the striking current, similarly regulates the distance by which the keeper can move away from the core by gravity or spring. As has been stated, the speed of the movement is controlled by the dashpot, and this can be regulated by means of a perforated disc in the piston. Consequently both striking and welding currents can be adjusted independently and the keeper is free to move between the stops under the control of an adjustable dashpot, so that the characteristic curve connecting volts and amperes is the resultant of the two curves which would have been obtained if the keeper had been fixed in either position. The consequence is that it is possible to weld with a lower open-circuit voltage and, in addition, to weld thinner material without burning through, as the striking current can be set so as to be very little in excess of that required for the actual welding operation. In working the firm recommend that the current for welding should be adjusted first and then the striking current reduced until there is just sufficient excess to enable the arc to be struck easily.

These welding machines are available in two standard sizes, one for currents between 25 and 100 amperes with infinite gradation, and the other similarly for currents up to 200 amperes. The machine is supplied as a complete unit ready for connection to the supply main, and any ordinary flux-covered electrode can be employed.

A.C. System.

The A.C. welding system is one which embodies novel features. The nature of a welding arc is such that the use of bare wire with alternating current for welding purposes is impossible unless special provision is made to counteract the effect of the periodic cessation of power.

Before the introduction of the A.C. welding system, the use of alternating current for welding purposes was condemned as inferior to D.C., and was only used in conjunction with heavy slag-forming electrodes.

A paper which was read before the Institution of Welding Engineers* explained the theory of arc stability, and showed the difference between the A.C. welding system and the transformer and fixed reactance stabiliser, which had hitherto been in vogue. It also shows that the tendency of the arc to die out is counteracted by the method of arranging the choking effect in the circuit as a variable quantity instead of being a fixed value. The 'Alternarc' transformer of the A.C. system can be adjusted to have a certain average value for its reactance, and this governs the average value of the power supply to the arc, in the same way as a fixed reactance choke coil is designed to determine the value of the power supply to the arc. The reactance of the 'Alternarc' transformer, however, is not a fixed quantity, but varies with the current over the whole load cycle, in such a way that when the current is at minimum the reactance value is a minimum, and *vice versa*.

The effect of this method of arc control is to give very high arc stability; so high, in fact, that it is claimed possible to do equal, and even more efficient, welding work with alternating current than with direct current.

Alternating current has been condemned for welding on many occasions, owing to the fact that the arc stability factor supplied by the transformer and choke combination was so extremely low. This bad feature of poor arc stability has now been overcome by the A.C. system, and consequently, with maximum welding efficiency possible with alternating current, coupled with the desirable features of high electrical efficiency, portability, and low first cost, the A.C. welding system offers a most efficient and economical welding system.

The way in which the variable reactance control is arranged is as follows:—The 'Alternarc' transformer consists of a primary winding wound on one limb of a closed core, having two secondary windings, one of which is wound to have high mutual inductance and low leakage inductance with the primary coil, and giving a heavy leakage flux on full load. In some cases an alternative path is arranged for the leakage flux by extending the core yokes between which extensions a movable flux-diverter is arranged. Both sections of the primary windings are tapped at intervals to give adjustment to the voltage and also to the current, the movable flux-diverter giving a fine adjustment for accurate work

The material used in the construction of the transformer is fireproof, the windings being composed of asbestos-covered wire, insulated with pure mica. Each of the larger type machines is provided with a cooling fan, and is enclosed in an oak case arranged with Sedan handles, in such a way that the whole apparatus is a portable unit.

To summarise, the claims made by the A.C. Welding Company for their system are—maximum welding efficiency, maximum arc stability (giving the choice of any electrode on the market); maximum electrical efficiency (giving minimum running cost); minimum upkeep (there being no adjustments of brushes, attention to commutators, etc.), and no maintenance charges. The machine is guaranteed against burning-out, and can only break down under wilful bad treatment.

The machines are normally supplied with an open circuit voltage ranging from 60 to 100, according to the settings of the secondary connections, but if required they are supplied with a standard 'Alternarc' safety device, which limits the open circuit voltage to a maximum of 25 volts.

Electrc arc cutting has been developed on the A.C. system. The system of cutting consists in the use of special cutting electrodes, which liberate free oxygen at the arc, steel being the basis of the electrodes on currents of 300 amperes, and carbon on currents from 600 to 1000 amperes.

Fluxode System.

The Fluxode system, Engineering Developments, Ltd., uses flux-covered and bare-wire electrodes which can be used with any arc welding plant. Mild steel, high carbon and manganese electrodes of both types suitable for high-class welding with high tensile strength or where a hard deposit, such as for reinforcing or building up tramway and railway rails, is required.

Arc welding plant to meet all conditions and for use on alternating or direct current has been designed from the point of view of economy and efficiency. The single operator set, for example, is suitable for any standard voltage on direct or alternating current supply varying from 100 to 500 volts. The set consists of electric motor coupled to a specially wound welding generator which possesses a variable voltage characteristic similar to that obtained by the combination of

a level voltage supply with a stabilising resistance in series with the arc. There is a reduction of about 50 per cent. in the cost of electrical energy as compared with the ordinary generator using a stabilising resistance. Owing to the special winding, an unskilled operator can make a much more efficient weld than with the ordinary generator.

Electric Blowpipe Welding.

In this process the electric blowpipe is essentially a horizontal-flame arc lamp using two carbons mounted like the letter V. The process was introduced by Dr. Zerener in 1890, and is usually known as the Zerener system. The flame of the arc was directed away or deflected downwards by means of an electro-magnet in series with the arc. The apparatus is bulky and complicated and for even moderate-sized work it must be suspended from above. This method of welding eliminates the passage of the current through the work. It is in use in several plants in Germany. The Voltex Process is a variation of the Zerener method in which the carbon electrodes are impregnated with metallic oxide which is vaporised by the flame of the arc.

Arc Welding Equipment.

Electric-arc welding may be done with a direct-current or alternating-current arc, having a reasonable degree of stability and sufficient amount of heat to accomplish fusion. The effect of the 'type' of current on the efficiency of metal deposition by the arc is threefold. It affects the speed of deposition, the amount of penetration or fusing of the metal, and arc stability. The design of the welding generator or transformer affects the cost of welding. The necessity for a special machine rests upon economic factors, and the differences between the various types used are differences of power, cost of operation, difference of speed of operation due to the relative stability of the arc.

The question of direct or alternating current raises many interesting points which have never been clearly determined. Good welding can be done with both direct and alternating current. Flux-covered electrodes are essential for certain types of alternating current machines, apparently because the lagging effect of the flux and slag maintains the necessary temperature during the periodical current reversals. Comparative data by independent authorities is missing, and the question of whether direct-current welding is faster or slower, whether flux-covered electrodes enable direct-current to take the lead in welding speed, whether the practical losses in motor generator and resistance compare favourably or otherwise with the alternating-current system, etc., etc., are questions which are answered by contradictory claims by both parties to this controversy. However, there are advocates for both systems, and suitable equipment can be obtained for arc welding with direct or alternating current.

The successful application of arc welding is largely dependent upon the selection of the proper equipment. There are two systems in general use—(*a*) single operator system, where a separate machine is provided for each operator, each machine receiving its current supply from the supply circuit; (*b*) multiple operator system, where more than one operator receives current direct from the same machine, but each operator is provided with a control panel which enables him to vary the current without interfering with the other operators.

The equipment consists of a motor generator, control panel, and accessories. When using alternating current use is made of a transformer to reduce the distribution voltage to that suitable for the weld. The various types of arc-welding apparatus have been described by Major J. Caldwell in a paper presented to the Institution of Electrical Engineers on December 14, 1922.

Amongst the accessories are protective equipment and electrode holders.

Protective Equipment.

The intense glare emitted in the process of arc welding consists of a combination of invisible infra-red rays, visible light rays, and invisible ultra-violet rays, and special safety devices are required to protect the operator from their harmful effects. For light electric welding it is necessary only to protect the eyes with goggles fitted with suitable coloured glasses. Hand shields are made for medium-weight electric welding work which can be done with one hand. They serve the double purpose of protecting the eyes of the operator and also shielding the face from the heat rays and ultra-violet radiations. For heavy electric welding it is common practice to use a helmet or hood which provides protection for the eyes, head, face, and neck, and leaves the hands free. With regard to the tint of the protective glasses, a reference to the note on goggles in the section on oxy-acetylene welding will be useful. For the protection of the hands and wrists leather gloves are used. These devices are subject to modifications to meet the requirements of special work. Neighbouring workmen and operators should be protected from the dangerous rays of the electric arc.

Precautions in Arc Welding.

The precautions that should be observed in arc welding have been set forth in a memorandum issued by the Factory Department of the Home Office (Form 329, June 1921). These deal with: (*a*) hand-screen; (*b*) helmet or mask; (*c*) gloves; (*d*) aprons; (*e*) protection from hot metal: (*f*) chipping of slag. The memorandum also deals with the comparative dangers of direct and alternating currents, use of direct current, injurious effects of radiations, etc.

Automatic Arc Welding.

Depositing metal using an automatic feed for the electrode results in a materially increased rate of deposition. Machines have been developed which are capable of welding steel 0·109 inches thick at the rate of 22 ins. per minute This method of depositing metal is particularly advantageous on sections of uniform shape upon which a considerable amount of metal is to be deposited. Automatic welding does not eliminate the human element in welding, but does in certain cases greatly increase the speed of the process, and in other cases obtains results which are beyond the limitations of manual operation. Automatic welding with the bare metallic electrode is in more general use at present than any other method. In one type of machine the electrode is fed to the arc from a reel by means of feed rolls actuated by a 30-volt motor which is shunted across the arc when the arc is struck. Regulation of feed is maintained by two contactors which change the direction of rotation of the feed motor when the arc voltage increases or decreases above or below a certain amount. A number of welding applications involve all the requirements of automatic welding except that the size or weight of the pieces to be welded prohibits convenient handling, clamping, and traversing. In such cases a semi-automatic welding machine has proved to be of great advantage. One type of machine feeds the welding wire through a flexible conduit to a welding nozzle in which the control switch for the feed motor is located. This control mechanism operates to start and stop the feed motor. The maintenance of a uniform and steady arc depends on the operator.

A recent development is the automatic carbon arc welding machine. In this machine the welding wire is placed on the work before welding. The heat of the carbon arc fuses both the wire and base metal forming the weld. Very high speeds are thus made possible.

SPEED OF WELDING IN FEET PER HOUR.

Thickness of Metal.	Hand Welding.	Semi-Automatic Welding.	Automatic Welding.
$\frac{1}{16}$	—	25 to 50	50 to 100
$\frac{1}{8}$	7 to 16	15 to 30	30 to 50
$\frac{3}{16}$	6 to 12	12 to 25	20 to 35
$\frac{1}{4}$	5 to 10	8 to 15	10 to 25
$\frac{3}{8}$	3 to 5	5 to 8	5 to 8

Arc-welding Applications.

The application of arc welding to repair and manufacturing is very extensive, but its application should be made with a full knowledge of the possibilities and limitations of the process. In the welding of iron and steel, with their great variety of physical properties, a familiarity with the wide range of conditions is necessary to meet and solve the problems presented. In welding cast iron, copper, brass, aluminium, etc., the application of arc welding should be looked upon as in the development stage where welds with physical, chemical, and mechanical properties similar to the base metal are required.

A complete investigation into the welding of cast iron is at present being carried out, and the results, as far as they have gone, demonstrate that it is possible to weld some grades of cast iron if the proper method and conditions of welding are obtained. The following points have been considered :—(1) Preparation of the parts ; (2) prevention of slag inclusions ; (3) suitable values of current ; (4) method of deposition and its effect on the strength and hardness of the weld ; (5) reversed polarity versus straight polarity ; (6) effect of long versus short arc ; (7) effect of speed on the softness of the weld ; (8) the hard zone and its removal ; (9) relative weldability of various grades of cast iron ; (10) tests of electrodes. There is a great need at the present time for data on these various points.

Cost of Arc Welding.

The cost of electric arc welding with the metal electrode process depends upon several variable factors, such as : (1) the price of labour ; (2) the characteristics of the arc, (*a*) arc easy to maintain, (*b*) arc difficult to maintain, (*c*) amount of heat available ; (3) the cost of power ; (4) the cost of electrodes ; (5) supervision required, (*a*) production work, (*b*) work of a varied character ; (6) interest charge on equipment.

Welding speed is fundamentally dependent upon the rate of metal deposition. This rate varies with such factors as, energy required for liquefaction of electrode material, arc stability, current density, and electrical resistance of electrode material. It has been shown that high current welding results in an increase of 100 per cent. in the speed of welding a butt joint. Butt joints in ½-inch plate may be welded at a maximum rate of 5·3 ft. per hour when employing 175 amperes; at 10 ft. (or more) per hour when using 400 amperes.

See also 'Electric Welding,' Vol. ccviii (April 1921), *Proc. Inst. C.E.*

RESISTANCE WELDING.

There is a marked distinction between the joining of metals by the two electric processes, viz., arc welding and resistance welding. In the former the heat is localised through the action of the electric arc and no pressure is applied; in the latter the heat is localised by the resistance to the flow of the current and pressure is used.

The process of resistance welding is based upon the phenomenon that a poor conductor of electric current will heat if current is forced through it, or that a good conductor will also heat if enough current is passed through it, and that the heating effect will be greater if alternating current is used than if direct current is used. Since an imperfect joint, such as the abutting ends of two pieces of metal, or the lapping of two pieces of metal which are to be welded, is a poor conductor and offers great resistance to the passage of the current it will naturally heat and finally cause the metal to fuse and flow sufficiently to weld. In practice the operation is very rapid because comparatively large amounts of current are used.

For this type of welding a single-phase alternating current of any commercial frequency is used. The transformer in the machine will take the current from an ordinary shop circuit and reduce it to a suitable welding current.

Resistance welding is only suitable for duplicate or repetition work. In general one machine is designed for handling pieces of the same metal and for making joints of similar design. Repair jobs have been done in special cases but it is only in rare cases that such an adaptation is attempted.

A resistance welding machine is simply a single-phase transformer having a secondary of one or two turns, the voltage required between the terminals being only five to ten volts, and the current being limited only by the size of the pieces to be handled. The transformer is built into a heavy frame which supports the clamping jaws to handle the work and mechanical devices to regulate the heat and pressure. The machine has reached a high degree of perfection, and large savings of time and labour have resulted in production work. The principle involved has been applied in the construction of a variety of machines.

By some one of the resistance welding processes, nearly all metals and alloys can now be welded. Tin is the notable exception. The cross section of stock that t is possible to weld by the resistance process now seems to be limited only by the electric power available. Special adaptations for heating rods, bars, billets, rivets, etc., and electric brazing and soldering machines are available. Special machines for zinc tube welding, automatic spot welding, rivet heating, forging hearths, welding hollow articles, etc., etc., have been placed on the market by Engineering Developments, Ltd., and their main features have been dealt with in a paper recently read before the Institution of Welding Engineers.*

Butt Welding.

Consists in joining pieces end to end, securing complete fusion of the entire cross-section of the pieces. The pieces to be welded are placed in the clamping jaws, one of which is stationary and the other movable; enough pressure is exerted to bring the ends into contact and the current is then turned on. As soon as the welding temperature is reached the operator increases the pressure, thus forcing the pieces together, and turns off the current. Nearly all metals used commercially have been welded by this process.

Butt welding may be subdivided into three classes, namely, (1) upset welding, (2) flash welding, and (3) contact flash welding or automatic butt welding.

As regards the first subdivision, in which the weld is made by butting the cold ends of the stock to be welded and then applying the electric pressure, it is apparently being superseded for most purposes by flash welding.

Flash welding is made by applying the current before the ends are in actual contact and utilising the flash or minute arcs that play between the ends of the stock. Some advantages of flash over upset welding are (*a*) less power required, (*b*) less extrusion or upsetting, (*c*) burnt metal is thrown off, (*d*) increased production, (*e*) stronger welds.

The third subdivision, contact flash welding, is in some respects similar to percussive welding. The weld is made almost instantly by using high continuous contact pressure and heavy current, the current being cut off by automatic methods of control.

---

* 'Resistance Welding,' by F. E. Saunders, M.I.E.E.

Spot Welding.

Consists in pressing the pieces together while passing the current through them, and localising the flow of the current so that the weld is confined to 'spots' between the electrodes, which are used to secure the pressure. The term automatic spot weld is given to a spot weld made on a welder which applies the pressure, makes and breaks the circuit all automatically.

The material to be welded is placed between copper die points supported on the ends of two arms, and the points are brought firmly together on the metal by the use of either foot or motive power. The current is then turned on. The metal, being a poor conductor, becomes heated, and when heated to a sufficient degree, pressure is applied. In the case of automatic control, the current is turned on and off and the necessary welding pressure applied automatically by controlling mechanism usually driven by a variable-speed motor. The majority of commercial metals can be spot welded, but it is essential that the metal to be welded should offer a considerable resistance to the electric current, otherwise sufficient heat cannot be generated. The spot welding of light materials guarantees a successful product and increased production. A commercial spot welder for $\frac{1}{4}$-inch plates is in use.

During the past few years considerable investigation has been carried out with regard to heavy spot welding for ships and constructional work. Large machines capable of supplying a welding current up to 100,000 amperes, and equipped to exert a pressure up to 30,000 lbs. per square inch on each spot, have been constructed. The main difficulties which have been encountered are, briefly, electrode-tip protection and the preparation of the materials to be welded. Two secondary considerations have been the separation of the electrodes and the shape of the head of the spot welder.

The following indicate the variations of spot welding:

Button and Disc Depression Welding.

Where very thick work is to be spot welded it is often desirable to find means to localise the current and cut down the amount of pressure required. Small metal discs or buttons can be used for this purpose placed between the head of the welder and the metal to be welded. Disc-depression welding differs from button welding in that in the disc-depression method an annular depression is provided in one of the sheets, around the disc. The method makes possible the use of a comparatively light machine for welding heavy steel plate, and also the use of less power and time for making the welds.

Bridge Welding.

Is used to join thin sheets edge to edge without overlapping and without reducing the dimensions of the pieces. The sheets are brought together in their correct position, and then thin strips or discs are spot welded across the joint.

Multiple Electrode Welding.

Time and power can frequently be saved by making several welds at once, in which case the spot welder is equipped with two or more electrodes. It is advisable to have projections on one of the pieces to be welded to assist in localising the current. Successful multiple welding requires a separate transformer for each weld.

Point or Projection Welding.

In this method the metal to be welded is provided with points or projections. The points are brought in line with each other, and the welding effect is to provide a smaller contact point which increases the resistance and allows the weld to be made with the consumption of less time and power. Ridge welding is the same as point welding, except that, instead of a single point a ridge is raised in the metals in such a way that the ridges on the two pieces come together in the form of a cross.

T Spot Welding.

When pieces are welded in the form of a **T** by holding one piece in a hollow electrode and welding it to the other the resulting weld is called a **T** spot weld.

Duplex Spot Welding.

In this type of spot welding two transformers are used simultaneously on opposite sides of the sheets to be welded and their currents pass through two secondaries, welding two spots simultaneously.

Combinations of all the above processes have been made for special jobs. Sometimes it is only necessary to make a change in the construction of the electrodes to make a machine do work of a varied character.

Seam or Line Welding.

Consists in joining pieces along a continuous line or seam, usually by moving the joint in the path of the current, so that fusion is secured continuously. The process combines the features of butt and spot welding. Machinery has been developed very successfully, but is limited to work on light stock and short seams. Standard seam welders are usually equipped with two electrodes, one connected to the work and the other a roller running over the seam, or both electrodes may be converging rollers, with the converging edges resting on opposite parts of the work near the edge to be welded. The work is passed beneath the rollers, which carry the current into the metal, and makes a continuous line of welding. The work must be carefully cleaned and be securely held by the machine to get good results.

Considerable development work has been done during the past two years. It has been applied to the manufacture of steel barrels, casks, tanks, ventilators, heating and ventilating pipes, etc. Seams can be made at a rate of 40 ft. per minute on $\frac{1}{16}$ in. sheets, and 20 ft. per minute on $\frac{1}{8}$ in. sheets. The welds may be butt, lap, or bridge, and be made continuously or progressively.

Mash Welding.

Mash welding is a process of welding rods, wires, strips, etc., by crossing or overlapping the pieces and welding between relatively large electrode surfaces under pressure.

Electro-percussive Welding.

This is a process which is chiefly intended for manufacturing applications in which large quantities of duplicate parts are to be produced. The underlying principles utilised in percussive welding were discovered in 1905 by Mr. J. Chubb, of the Westinghouse Company. Following his original experiments, machines were developed for welding metals in wire form of rather small cross-section. Widely different physical properties offered no obstacle, and ductile welds can be made with copper and aluminium, platinum and lead. Electrical devices are used whereby a rapid small separation of the parts to be welded causes an intense arc to melt the surfaces. At the proper moment a forging hammer forges the pieces together. The advantages claimed for the process are (*a*) power saved ; (*b*) time of welding negligible ; (*c*) welds of unequal sections are possible ; (*d*) welds of unlike metals can be made ; (*e*) uniform welds ; (*f*) cost of finishing welds reduced. Recent results have shown that percussive welding has many valuable applications, especially in non-ferrous and steel-alloy welding.

Experimental work has been directed toward extension of the process to larger cross-sections. A large impulse transformer has been built capable of storing 20,000 joules. Sections up to $\frac{3}{4}$ in. diameter have been successfully welded and no apparent limitations are anticipated from a process point of view.

ELECTRIC CUTTING.

Although cutting with a blowpipe has many advantages over electric arc cutting, yet there are many places where the electric arc can be used advantageously. The groove is not so narrow as that cut with a blowpipe, nor is the surface cut as clean.

The electric arc will cut any metal, ferrous or non-ferrous, and has been found particularly useful for the cutting of cast iron. The thickness that can be economically cut by the arc varies from 4 to 6 inches, for straight cutting. The current necessary for cutting operations on general and heavy cutting varies from 800 to 1,200 amperes. The voltage of the cutting arc varies between 25 and 45, a good average being 37.

It will be seen that heavy values of current are required, and special apparatus has been designed so that the arc could be controlled with these heavy currents. An important part of these developments is the design of a handle to protect the operator, hold the electrode, and to carry 1,000 amperes. A small item like the use of pure graphite instead of carbon for electrodes means the difference between success and failure.

Increase of current means larger electrodes and hence more metal to be cut out. The latest development for this work is a low resistance graphite and the approximate sizes for various current densities are as follows :—200 amperes, $\frac{1}{4}$ to $\frac{3}{8}$ in. electrodes ; 300 to 400 amperes $\frac{3}{8}$ to $\frac{1}{2}$ inch electrodes ; 400 to 600 amperes, $\frac{1}{2}$ to $\frac{5}{8}$ in. ; 600 to 800 amperes, $\frac{5}{8}$ to $\frac{3}{4}$ in. ; 800 to 1,200 amperes, $\frac{5}{8}$ to 1 in. electrodes.

Cutting on heavy sections is generally best accomplished from the underneath side or from a vertical face tipped slightly greater than 90 degrees so that the molten metal can flow away, although the action is not entirely simply melting metal. In cutting with the arc a reasonably smooth surface can be made by paying attention to one side only, or the cut may be made rough and trimmed up smooth by a second application of the arc.

Recent developments consist of a special electrode for cutting with the arc, and for such work as piercing holes. This special electrode, covered with a coating giving off free oxygen under the temperature of the arc, gasifies the entire metal melted, so that the boring action is uninterrupted after once started. This electrode is used by starting the arc and immediately pushing the electrode into the puddle. After the hole is through the piece it can be widened to

any size or shape by drawing the arc around its edges. This type of electrode only takes from 250 to 350 amperes. The most recent development in under-water cutting is an adaptation of the carbon electrode arc cutting process, in which the carbon electrode is pierced by two small brass tubes, through which a special cutting gas is supplied from the surface. The gas oxidizes and blows away the metal melted by the arc, and also converts the surrounding water into steam, thus making a gaseous envelope for the arc. The combined action serves to greatly speed up the operation of the cutting electrode, as the metal is blown aside before it has a chance to solidify. This device has been used successfully for cutting metal between three and four inches thick at a depth of about 70 ft.

THERMIT WELDING.

This process consists in uniting the parts to be welded by pouring between them molten metal at a sufficiently high temperature to fuse them, so that on cooling union is perfected. The parts to be welded, where fractured, are cut away in order to leave a space for the molten metal. The Thermit mixture is composed of powdered aluminium and iron oxide. The two are intimately mixed, and heated at a point by a special ignition powder. At the temperature produced by igniting this powder, the aluminium reacts very energetically with the oxygen in the iron oxide. The reaction spreads rapidly throughout the mass in the crucible and produces a quantity of fluid metal, covered with a slag of alumina. The temperature set up by the reaction has been ascertained to be about 5,400° F. The crucible is a lined sheet-iron cone. It is suspended over the parts to be welded, and when the reaction is complete it is tapped, the metal running into the mould which has been built round the fracture. The weld is usually larger than the original section, and the mould may be made from a wax pattern fitted around the fracture. The wax is melted out with a preheating torch, leaving a space for the Thermit metal, and the parts then preheated to a bright red heat before tapping the crucible. Iron oxide produces a very mild material, and it is usual to mix in with the Thermit compound small pieces of steel and ferro-manganese in certain proportions, so that the metal produced is similar to ordinary mild steel.

The welding of tramrails is carried out by means of the Thermit process. The rail-ends are carefully butted at the joint, and the weld made by running (into a suitably shaped mould) the superheated liquid steel along the base and web of the rails, followed by a slag which covers the head of the rail and raises it to a welding temperature. The rails are then drawn together by special clamps, with the result that the base and web of the rails are welded by fusion with the liquid Thermit metal and the head is butt-welded.

SECTION XXXIX

EXPLOSIVES.

(Contributed by Professor W. R. Hodgkinson, F.R.S. (Edin.), Ph.D., F.I.C., C.B.E.)

Explosives may be classified into 'Propellants,' which are required to produce a rapid but steady rise in pressure in some kind of firearm; others may be termed 'Detonators,' or the less definite term 'High Explosive.' The latter are practically instantaneous in action and produce a wave or vibration of high velocity. Under certain conditions some substances may behave as belonging to either class.

The first propellant, 'Black Powder,' has since 1770 (about) consisted of nitre 75 per cent., charcoal 15 per cent., and sulphur 10 per cent. Practically all the gases, which may be 700 times the volume of the powder, arise from the nitre, the volume varying according to the density of the powder and to the conditions at burning.

Gunpowders do not detonate, but may give a very rapid rise of pressure if burnt in a closed space. Being porous, though dense, the first formed and very hot gases are driven through the remainder of the charge, igniting it *en masse*.

Cordite.

Cordites and the like are practically the most satisfactory propellants invented: owing to their gelatine-like structure they are non-pervious to gases. All true colloids show this property in some degree; the rate of burning can therefore be well regulated by the area of surface, volume of gas, and temperature. Owing to their composition, these explosives are practically smokeless. The cold-gas volume (i.e. volume at ordinary temperature) is in the region of 1,000 times that of the powder, and the temperature seldom less than 2,000° C., and may be above 3,000° C., according to composition. 'Cordite' proper consists of gelatinised high grade gun-cotton with a certain amount of nitroglycerine and a mineral jelly incorporated while the gelatinising agent is still present, the agent eventually drying off. A number of varieties of these powders are made with lower grades of gun-cotton, their physical properties being much the same. These powders are not easily detonated and are useless for blasting purposes.

Gun-cotton.

Gun-cotton' and 'Cellulose Nitrates' are made by the action of a cool mixture of nitric and sulphuric acids on cleaned cotton waste or the like. Strength of acids, temperature, and time of contact determine the extent and nature of nitration. Real gun-cotton contains about 13·8 per cent of nitrogen, nearly corresponding to $C_6H_7O_2(NO_3)_3$.

Varieties of nitrated cellulose containing 10 to 11 per cent., or less, nitric-nitrogen than real gun-cotton are also used in some classes of propellants.

Gun-cotton is unaffected by water and does not burn if containing about 10 per cent. of moisture. When dry it ignites at between 160° and 180° C. It burns without smoke and is easily detonated by a sharp blow on a hard surface. When wet it can only be detonated by a primer of dry gun-cotton. When pulped and pressed into slabs, gun-cotton (13·8 per cent. N.) is used for blasting: its action is very local.

Nitroglycerine.

Nitroglycerine is formed by the action of mixed nitric and sulphuric acids on glycerine at a low temperature. It is a colourless oily liquid of sp. gr. 1·6. It freezes easily, and melts at 4° C. It is practically insoluble in, and unaffected by, water. Solid or liquid, it is easily detonated by percussion or by heating to about 150° C., hence the danger of thawing the solid nitroglycerine. As a liquid it is unpractical as an explosive, but when mechanically absorbed into a porous inert material, or incorporated in the substance of a jelly, useful preparations result.

Dynamite.

'Dynamites' which fulfil most of the requirements for blasting, and are reasonably safe, consist of nitroglycerine incorporated in kieselguhr, cork charcoal, and the like non-gritty powders. Generally some metallic nitrate, colouring or binding dope is added. Dynamites can be detonated by fulminate detonators. They are comparatively safe to handle and store for a moderate time in a place of medium temperature. Water may cause the extrusion of nitroglycerine from most forms of dynamite.

Gelignite.

'Gelignites' are mainly a thin jelly of a low grade gun-cotton in nitroglycerine; warm nitroglycerine is usually the gelatinising agent, but others may be employed. They may contain about 90 per cent. nitroglycerine. They are plastic, waterproof, and more powerful and convenient than ordinary dynamites. They should be stored in a place of cool even temperature. Most of the gelignites are doped, for some real or imaginary object.

Permitted Explosives.

'Permitted Explosives' for use in mines are such that comply more or less perfectly to certain tests, such as non-ignition of fire damp or coal dust, not producing a dangerous amount of poisonous fumes, considerable range of safety in storage and use. In many of these explosives, ammonia nitrate is the main oxygen carrier, the combustibles being benzene derivatives such as nitrobenzene, nitronaphthalene, and the like, with or without wood meal or inert powders to cool the flash.

Perchlorate of ammonia is the chief active material in some blasting compositions for civil or military use (cheddites). They are useful in fiery mines, as a quantity of hydrochloric acid gas is produced on explosion which acts as a damper of flame. Almost any kind of organic matters may be used in this class. Paraffin wax is often used, as, amongst other properties, it is waterproof.

Perchlorate compositions are stable and keep well, but all are liable to explode on moderately strong percussion. Generally they simply burn violently on ignition by a flame.

Ordinary chlorate compositions should be completely barred, as they are never safe and are erratic in use.

Detonators.

Detonators are substances employed to start the disruptive explosion or detonation of other compounds which alone may not explode by a flame or a moderately hard blow. Owing to the extreme rapidity of their explosion, detonators initiate a molecular decomposition of the main explosive, or it responds to the wave blow of the detonator.

Mercury fulminate, $HgN_2C_2O_2$, is the oldest and most commonly used detonator. It may be used alone or diluted with nitre, antimony sulphide, potassium chlorate, or even inert substances in some proportion, in order to regulate its sensitiveness, or reduce or modify the manner of exploding.

Cap and igniting compositions contain same proportion of $KNO_3Sb_2S_3$ and $KClO_3$.

Small quantities of fulminate, say 2 grams, may flash off if fired open, but the flimsiest cover will cause it to detonate on firing by a flame contact. A very slight suddenly applied pressure causes detonation. Its function in cap compositions is to respond to the blow of the hammer and ignite the other ingredients.

Lead azide, PbN_6, acts similarly to fulminate, is stronger and quicker in action, but probably not so amenable to regulation as fulminate.

Fuses.

These are, generally, some arrangement for firing an explosive at a desired moment. They consist, as a rule, of finely ground black powder contained in a paper tube protected by tape, machine-wound over it and waterproofed by some resinous or pitchy composition. Rate of burning may be controlled by fineness of powder, and in some cases by its composition, diameter of tube, etc.

In military fuses the powder has to burn along a circuitous route of determinable length in a metal container.

Fuses for blasting are packed in barrels and cases containing 300 or 500 coils of 24 ft. length. The average rate of burning of safety fuses is 75 to 90 secs. per yard. (See also 'Trinitrotoluene.') The fuse end is inserted in the detonator cap, which is then secured in proper contact with the explosive cartridge or charge, which may be tamped in the bore hole or not according to nature of explosive. (See also 'Blasting,' page 2420.)

Lyddite, or Picric Acid.

Lyddite, or picric acid, $C_6H_2OH(NO_2)_3$, is mainly a military explosive. It is somewhat difficult to detonate, otherwise there is no reason against its use for rock blasting. When some quantity is burnt there is a liability for it to pass into the detonation stage. The chief danger in connection with it is the liability to form metallic compounds (picrates), which are extremely sensitive to heat, friction, or percussion. There are several related substances with similar properties and uses, such as dinitrophenol, nitrocresols, etc.

Trinitrotoluene.

Trinitrotoluene (T.N.T.) and trinitroxylene (and other stages of nitration of toluene, xylene, etc.) are mainly military explosives, but T.N.T. has been used for some time in instantaneous fuses for civil work. Under proper conditions all these substances could be used for blasting.

Amatols.

Amatols (of various catagories) are essentially ammonia nitrate compositions with T.N.T and similar substances. The violence of their explosion is increased by the addition of small quantities of powdered aluminium, magnesium, and other substances.

Amatols have a great future as blasting agents, but some of them are very sensitive and are not quite waterproof.

Blasting Machines.

Dynamo Electrical Blasting Machines (supplied by *Fleming & Company*, 31 *Robertson Street, Glasgow*) are specially built to explode all blasting charges with absolute safety, either in stone quarries, coal mines, or oil shale workings. Being water and damp proof they are always ready for action.

(All Parts by Weight unless otherwise Specified.)

PAINTING.

PAINTING WOODWORK.

A mixture of linseed oil and white lead is the best preservative of wood. The linseed is the preservative; the white lead gives body and opacity. Spirits of turpentine is added as a solvent, to enable the paint to penetrate into the pores of the material; the solvent should be light and easily evaporated.

Boiled linseed oil dries quicker than raw, but is darker and thicker than the latter.

TO REMOVE OIL PAINT.

2 lbs. washing soda, 2 lb. quicklime, mixed to consistence of cream, spread on, and kept moist for an hour. The paint can then be washed off.

GLAZIER'S PUTTY.

Whiting and raw linseed oil, well beaten up.

TO REMOVE OLD PUTTY.

Paint it with nitric or hydrochloric acid, and after about an hour it will be soft enough to remove; or a hot iron will soften it at once.

PAINTING.

In painting woodwork for the first time, kill knots with coating of fresh slaked lime; then in 24 hours scrape off, and paint knots with mixture of red and white lead and linseed oil; or use red-lead powder mixed with strong glue-size, and apply warm—the work can then be gone on with in a few minutes; when dry, smooth with pumice stone. Next put on priming coat. All holes are then stopped with glazier's putty, and the required coats added; each coat in good work is rubbed smooth with glass-paper before adding another.

Painting required to have no gloss has an additional coat, made with turpentine only, and no oil, called a *flatting coat*.

For old work, if much soiled, wash with soap and water and scour; if foul with smoke and grease, wash with lime and water; then commence with *second* coat.

New woodwork should have 4 coats; for periodical repainting 2 are sufficient.

PRIMING.

This generally consists of a mixture of white lead and red lead, irrespective of the colour to be used in finishing. The lead mixture is diluted with boiled linseed oil and a small quantity of turpentine. A special asbestos priming for painting fibro cement and all classes of asbestos sheeting is supplied by *Messrs. Walter Carson & Sons*, Grove Works, Battersea, London, S.W. 11.

'MURAPRIME.'

This priming (*Walter Carson & Sons*) is for use on porous plaster walls, for walls with unequal absorption, and for walls stopped with various plasters. Internal walls on which a perfect surface is desired should receive a coat of 'Muraprime' on the bare plaster. It assists to bind loose particles, and stops unequal absorption, which often makes flat painting or distempering patchy and unequal in colour. It is sold in four colours—white, yellow, green, and pink.

'Coverine.'

This paint (*Walter Carson & Sons*) is a white undercoating, which saves time in the preparation of undercoats. It is ready for use in five minutes, and requires to be thinned with turpentine only. One coat is equal to two coats of white lead paint, and is consequently a saving of time and material. It dries hard, and can be coated in a few hours. The finishing coat can be applied and the work completed in one day. It forms a good undercoating for gilding, and will stand washing.

'Muraline.'

This is a washable water paint (*Walter Carson & Sons*), and is sold in dry powder, in forty artistic shades. Water added to the powder in an equal proportion makes a sanitary washable paint, which forms a highly perfect and durable surface. Compared with paste distempers (which contain about one-third of water), it is claimed to effect a considerable saving, owing to its great covering power. 1 cwt. covers 600 to 700 square yards on non-porous surfaces. It will never deteriorate if stocked in a dry place, unexposed to the air. 1 cwt. of powder with 1 cwt. of water makes 2 cwt. of paint. It can be applied to new lime plaster, if dry, without injury to the colours. It works and flows evenly under the brush, and leaves a hard, smooth surface. Intermediate shades may be produced by mixing colours or by reducing with white. It is non-poisonous and an excellent disinfectant. The colours are fast to light, and do not discolour. It does not rub off, scale, or flake. The white is an excellent covering for ceilings. Unlike whitewash, removal is unnecessary before repainting if in sound condition.

PAINTING IRONWORK.

For new ironwork 3 coats Torbay or other oxide of iron paint answers well; 1 lb. mixed with oil will cover from 8 to 12 yards. For periodical painting, 2 coats. For the first, or first and second coats on iron, red lead is very generally used; 1 lb. mixed with oil will cover about 5¼ yards.

'Ferri-Silicon.'

This paint (*Walter Carson & Sons*), which can be made in any colour, is a cheap and durable preservative for ironwork, woodwork, and all exposed surfaces. It is a combination of iron and other oxides with silicates, which, when incorporated with a special enamel oil, produces a paint closely resembling enamel, but with a very tough and elastic surface, absolutely impenetrable. The manufacturing process which the enamel oil undergoes is claimed to render it at least twice as durable as the finest linseed oil. The paint is specially suitable for use on gasometers, as the colours are not affected by contact with sulphuretted hydrogen gas, sulphide of ammonia, etc.

'Anti-corrosion.'

This paint (*Walter Carson & Sons*) is for out-door work as a preservative for iron, wood, stone, brick, compo, etc. It is employed by many of the leading railways both at home and abroad, and also on life-boat stations. It is well adapted for coating the roofs of corrugated iron buildings, etc., and is especially recommended for buildings exposed to the corrosive action of sea air as it does not blister and wash off under these trying conditions.

Syronite Anti-Rust Paint.

Syronite is a thin transparent syrup which can be painted upon new ironwork before, during, or after erection, or upon existing structures that are already rusting. If the structure is in a bad state before the Syronite treatment is undertaken, the surface is first well brushed with a stiff wire brush to remove all loose rust. A coat of Syronite is then applied, its action being to penetrate through any remaining rust and cause this to shed off. When shedding has taken place, another coat is applied, and then the treatment is complete.

Pigments can be combined with Syronite when required.

A peculiar feature of the material is its capacity of 'creeping' or spreading. Ordinary paint stays exactly where the brush leaves it, and as the brush cannot always get under and along joints, round rivets, etc., these parts do not get equal protection with the general surface, but Syronite on a metal surface will permeate into every crevice, thus effectually insulating the iron and protecting it against corrosion.

Minerva Bright-part Coating and Rust Preventive.

This preventive is intended for brushing on machinery bright parts prior to leaving the foundry or finishing shop, to prevent rust forming during transit and erection. It dries almost immediately with a firm, elastic, damp and acid-resisting surface that will not come off through ordinary handling. When it is desired to remove the coating, it is only necessary to wipe the surface over with a cloth damped with turpentine, petroleum, or benzine, when the coating will at once disappear and the parts can then be polished up to a bright condition.

PAINTS

For preserving IRON, STEEL and WOOD WORK, and for the finishing of all High-class Machinery.

PAINTS

Made to suit the requirements of ALL BUYERS.

Aquatinto Distemper

For Workshops, Factory Walls, and all Domestic Decorations.

For Samples and Full Particulars please apply:

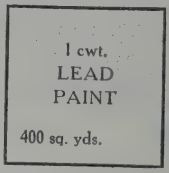
Foliac Silica-Graphite Paint

Diagram showing relative covering power of Lead Paint and Foliac Silica - Graphite Paint.



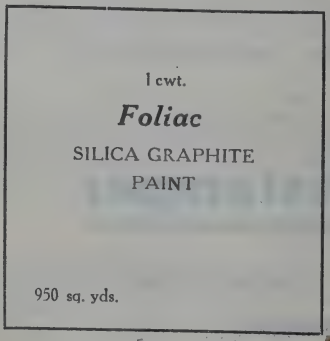


Diagram showing relative rates at which Lead Paint and Foliac Silica Graphite Paint can be applied.

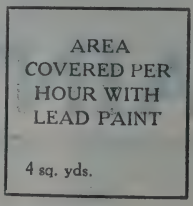

Diagram showing relative cost of Lead Paint and Foliac Silica Graphite Paint supplied to plane surface, assuming equal life to both paints

THE COSTS ARE PROPORTIONATE TO LENGHTS SHOWN

A similar saving will be found over Iron Oxide Paints

In addition to the above advantages, consideration should be given to the proven greater life of Foliac Silica Graphite Paint

Minerva Machinery Finishes.

These finishes embrace one, two, and three-coat work. For loose or rough metal with surface defects, air-holes, etc., an iron-filler, known as 'Indurine,' is used straight in the plastic form supplied. It is spread with a knife or leather over all bad places, so as to bring them up to the proper level, and sets 'iron hard' very rapidly. For clean castings the 'Indurine' is thinned down with 'Indurine Blender' until of a suitable consistency for brushing on. Thus applied it will bring the whole surface up level and hard, ready for sand-papering smooth to take paint. In addition its anti-corrosive character acts as a preventive against rust.

Minerva 'Intermediate Coat' is a glossy black made with a special medium and supplied in ready-to-use consistency. It is brushed direct on to the filled iron after first removing all traces of oil, grease or dirt. On account of the special medium employed in its manufacture, it grips tenaciously, dries quickly with a tough, elastic surface that is grease, oil, spirit, and acid proof, and which will be affected neither by sulphurous nor other chemically laden fumes. For an extra substantial effect, a second coat of this paint can be applied when the first is quite hard and dry.

Minerva 'Finish' is made in four standard shades from grey to black. This paint is applied upon the 'Intermediate Coat' when this is bone dry. It spreads freely, has great covering capacity, and dries rapidly with a solid, grease and oil-proof surface—perfectly flat, half gloss and full gloss finish.

Preservative for Ironwork.

(1.)

Coal-tar boiled till the watery vapour and naphtha are expelled, and mixed when cold with ½ pint of naphtha and the same amount of boiled oil to each gallon of tar.

(2.)

Experiments carried out by the Military Engineering Department at Brest have shown that as an effective preservative for metal work coal tar is rendered far more efficient by the addition of a small quantity of quicklime, in the proportion of one part of lime to two parts of tar. The mixture, after being heated to the boiling point, is brushed upon the ironwork at a temperature of about 120° F. The tar should be used over a coating of red lead.

(3.)

A valuable rust-inhibitive coating for general priming or finishing work may be prepared from sublimed blue lead. Two parts of blue lead and one part of linseed oil containing about 5 per cent. of turpentine drier make a paint of the right consistency. When this paint is used for top-coat work in marine exposures—battleship gray—the addition of 1 per cent. of carbon black to the blue lead aids in the maintenance of the colour.

Rust Proof Coating for Iron or Steel.

Linseed oil, 25 parts; calcium resinate, 36 parts; manganese borate, ½ part; lead acetate, 1 part; naphtha, 37½ parts; artificial graphite, 25 parts. These are mixed and applied to the metal by brushing, or dipping, or any other method. The article is then baked at 300° F. for 1 hour and 40 minutes. The coating is highly lustrous and resistant to corrosion.—*American Machinist.*

Note on Iron-work Painting.

According to experiments published in the *Bulletin de la Société des Ingenieurs Civils de France*, a number of coats of paint form a much less effective rust preventive for metal than a single layer does. Iron plates well cleaned and polished were coated, some with one coat and some with two, three, or more coats of paint, and then exposed to the action of steam for a whole day, after which the paint was removed and the plates were examined. The first was as bright as it was before exposure to steam, the second showed a few rust spots, the third was still more attacked, and the fourth entirely so. This result is stated to be due to the fact that the deeper layers dry badly and tend to dissolve the uppermost coating, increasing its porosity to air and moisture.

Painting Zinc.

Dissolve 1 part chloride of copper, 1 nitrate of copper, and 1 sal ammoniac, in 64 of water, and add 1 part commercial hydrochloric acid. Paint the zinc with this, and leave to dry for 24 hours. Any oil colour will then firmly adhere to it.

To Paint in Imitation of Ground Glass.

White lead, 4 parts; boiled oil, 3 parts; spirits of turpentine, 1 part; add a small quantity of dryers. The colour must be exceedingly thin, and put on the panes of glass with a large brush in as even a manner as possible. Dab the paint over lightly with a pad of cotton-wool covered with an old linen rag.

Hydraulic Cement Paint.

Hydraulic cement mixed with oil forms an incombustible and waterproof paint for roofs of buildings, outhouses, etc.

Outside Whitewash.

Slaked lime, ½ bushel. Add common salt, 1 lb.; sulphate of zinc, ½ lb.; sweet milk, 1 gallon.

Flexible Paint.

Used for painting on canvas. 2½ lbs. good yellow soap dissolved in 1½ gallon boiling water grind the hot solution with 3½ gallons of good oil paint.

Red Paint, quick drying (8 to 20 Minutes).

(Used for Pillar-boxes.)

Japanner's gold size	40 per cent.
Red lead	60 „

When dry, varnish with outside oak varnish.

Waterproof Paints.*

For General Purposes.

(1.)

2 gallons linseed oil, boiled with 11 ozs. each of rosin and litharge, 1½ oz. each of minium and umber; add gradually 8 ozs. of sulphate of zinc and a solution of 12 ozs. of potassium hydrate, and a like quantity of alum in 4 gallons of water. For preparing the ground colour, compound 10 lbs. of chalk and 2 lbs. of zinc white with ¾ gallon of water in which 1½ oz. of alum has been previously dissolved, and mix with this a solution of 1½ lb. of glue in ¾ gallon of water. This ground paint is mixed with 4 to 5 lbs. of the above composition, and the mixture diluted with petroleum.

(2.)

12 ozs. of melted rosin, thoroughly mixed with 6 gallons of fish oil and 1 lb. of melted sulphur, and some ochre or any other colouring substance rubbed up with linseed oil. Apply several coats of the hot composition with a brush. The first coat should be very thin. Suitable for either wood or stone.

For Casks and Waterspouts.

Boiled oil, 1 part; charcoal, finely powdered, 1 part. Mix to consistence of paint.

For Vessels and Submarine Works.

Sulphate of copper, 400 lbs.; grape sugar, 100 lbs.; concentrated solution of potash, 200 lbs. The precipitate of hydrated oxide of copper formed by heating this mixture is filtered, dried, and mixed with 8 lbs. of 75 per cent. carbolic acid. Heat the mass moderately, and add about 12 gallons of crude linseed oil. When the paint is to be used it is reduced with linseed oil, and then applied. This composition is claimed to prevent the deposition of marine animals on the surface to which it is applied.

Paints for Waterproofing Outside Walls.

(1.)

Rosin, 4½ ozs.; litharge, 3 ozs., boiled in 1 pint of clear linseed oil until the wooden spatula used for stirring becomes brown. Give the walls 2 or 3 coats of this, preferably on a hot and dry summer's day.

(2.)

A solution of paraffin wax in heavy coal-tar oil is excellent for painting houses, and especially walls exposed to the action of the weather. Several experiments in painting damp walls with this solution have given very satisfactory results. Wall-paper which formerly became moist and detached from the walls during rainy weather remained perfectly dry after the wall had been painted with this solution, which is prepared by dissolving 1 part of paraffin wax in 2 to 3 parts of coal-tar oil at a moderate heat. A sufficient quantity of oil must be used so that the solution does not entirely congeal on cooling. To heat the paint while applying it, place the vessel containing it in hot water. It is best to apply the solution on a warm day, when the bricks are dry. Generally 1 coat is sufficient, but even if 2 coats are given the cost is considerably less than that of oil paint.

Paint for Wooden Floors.

Soak 2 ozs. good light-coloured glue in cold water for 12 hours, and dissolve it with constant stirring in thick milk of lime (prepared from 1 lb. of caustic lime) heated to the boiling-point.

---

* It has been proved that no paint film, of which linseed oil is one of the chief constituents, can be made *thoroughly* impervious to moisture.

Stir in 8¾ ozs. linseed oil. Mix with any colour not affected by lime, and dilute with water if necessary. For yellow-brown or brown-red colours, boil in the ground colour ¼th of its volume of a solution of shellac and borax. A coat of varnish produces a bright surface.

Paint for Red Brick Floors.

Wash the bricks with soap-water containing $\frac{1}{10}$th part of carbonate of soda. Dissolve 1 part of glue in 16 of boiling water and 4 parts of red ochre, and stir the mass thoroughly together. Apply 2 coats of this to the bricks, and then give a coat of linseed oil varnish.

Preservative Solution for Stonework.

1 part white shellac, dissolved in 8 parts wood spirit. Apply to surface by means of a watering pot provided with a rose.

Paint for Roofs.

Pulverised slate (argillaceous schist), 35 parts; pulverised mica slate (mica schist), 30 parts; pulverised rosin, 35 parts; mix with ½ its volume of pure coal-tar, and boil to a fluid mass. This paint gives a very durable and pliant coating, which does not melt in the greatest heat of summer nor crack or break in the greatest cold. It resists moisture, and retains its lustre and smooth surface. It will last for 4 or 5 years.

Paints for Preserving Wooden Posts.

(1.)

50 parts rosin, 40 parts powdered chalk, 4 parts linseed oil; melt together in an iron boiler, add 1 part of natural cupric oxide, and stir very carefully into the mixture 1 part of sulphuric acid. Apply with a stiff brush. When dry the mass forms a coating as hard as stone.

(2.)

1¾ part rosin (melted), 48 parts fish oil, 1½ part sulphur. When the mixture is thoroughly combined and liquid, add sufficient ochre rubbed up with linseed oil to give the desired shade of colour. Apply the mass while still warm in as thin a coat as possible, and in a few days, when the first coat is dry, repeat the operation.

Paint for Felt Roofing.

Washed graphite, 2 parts; red ochre, 2 parts; cement, 16 parts; barium sulphate, 16 parts, plumbic oxide, 6 parts. These materials to be ground in an oil varnish prepared as follows: 100 parts of good linseed oil are boiled for 8 hours in a copper boiler with 5 per cent. of pyrolusite. 10 parts of flowers of sulphur and 20 parts of French pitch are then dissolved in the mixture, and the mass filtered before it becomes cold. 25 lbs. of this composition and 1½ gallons of linseed oil varnish or linseed oil, for reducing the paint, are sufficient to give 2 coats to 1,000 square feet of roof surface. The first coat, while still wet, is uniformly covered with fine dry sand by means of a sieve. The sanding should be done during the progress of the painting, so that the workman is not obliged to step on to the wet paint. The free sand is renewed with a broom before the second coat is given, and it is best to apply this 8 days after the first. The second coat need not be sanded, its purpose being to combine with the first to form an insoluble mass hard as stone, and to give to the roof a neat, finished appearance.

Quickly-drying Oil Paint.

Boil for 15 minutes in an earthenware pot 1 part of soft curd soap in 3 parts of water. Pour the mass through a colander, wash it with cold water, and press out the water in a linen cloth. To 1 part of the curd soap add ¼ part of unslaked lime and ¾ part of water. Triturate the fat slime thus formed in oil or water with the necessary pigments. Walls, ceilings, stairs—in short, anything of stone, plaster of Paris, or zinc—can be painted with this. If the paint is to be used on wood, add $\frac{1}{10}$ part of linseed oil. Ochre, chrome yellow, Berlin blue, indigo, lead, and zinc, are best adapted for colouring substances. The mixture dries so quickly that 3 coats can be applied in a day. It is entirely without odour, and is about one-third the cost of ordinary oil paint.

Fire-resisting Paint.

(1.)

20 lbs. finely pulverised glass, 20 lbs. finely pulverised porcelain, 20 lbs. any sort of stone in powder, 10 lbs. calcined lime, and 30 lbs. water glass (silicate of soda). The solid elements having been powdered as finely as possible and sifted, are moistened and then intimately mixed with the water glass. This yields a syrupy mass that may be employed for painting, either alone or mixed with colour. The coating is applied with a brush, as other paints are, as uniformly as possible over the surface to be protected. The first coat hardens immediately, and a second one may be applied 6 hours or more afterwards; two coats are sufficient. The paint must be used immediately after it is made up.

(2.)

The most practical means so far discovered by the United States Forest Products Laboratory, Madison, Wis., for economically rendering small quantities of wood fire-resistant consists in the

use of fire-retardant paints. Ordinary whitewash or calcimine has proved in tests to be as fire-resistant as any paint covering tried, and it also possesses the advantages of cheapness and ease of application. While it will not prevent the burning of wood continuously exposed to a high temperature, a good coat of calcimine will decrease the likelihood of a blaze spreading from small sources of fire, such as flying sparks and matches. Calcimine is naturally more effective for interior than for exterior use. For work of the latter class the Forest Products Laboratory has developed an effective paint composed of linseed oil, zinc borate, and chrome green, which has maintained its fire-resisting properties through more than three years of exposure to the weather.

Heat-indicating Paint.

A paint for indicating an excessive rise of temperature in machinery bearings is composed essentially of a mixture of the double iodide of silver and mercury and copper mercuric iodide. The former is a pale yellow powder at normal temperatures, but turns to a vivid carmine at 90° to 100° C., while the copper salt, which is normally of a strong scarlet vermilion, changes to a chocolate brown at 60° to 70° C. A mixture of the two in the proportion of 85 per cent. of the copper salt and 15 per cent. of the silver changes promptly from vermilion to nearly black at 60° to 70° C. The paint is made with the aid of white shellac spirit varnish (100 grms. of the mixture to 70 cub. cm. of the spirit), and is applied in the form of a band or bull's-eye to the bearing. After the paint has become dry it is to receive a coat of colourless oil-proof varnish.

See also p. 1010.

Painting Portland Cement.

Portland cement work which is to be painted must be thoroughly hardened and dry. It is advisable to let the work stand for a year before oil paints are applied. The durability of the paint will be assured by, first, brushing over the surface with dilute sulphuric acid—one part of acid to 100 parts water—and allowed to dry before painting. A preparatory coating for oil paint is a solution of common water glass in three or four parts of water. Two applications of this, followed by a washing with water, and then another application of water glass, will be found effective.

Coal-Tar Paint.

(1) Coal-tar, 8 parts; Portland cement, 1 part; kerosene oil, 1 part. (2) Coal-tar 16, Portland cement 4, and kerosene 3 parts. The Portland cement neutralises the action of the tar on iron and steel, while the kerosene acts as dryers. It is suitable for painting ironwork of all kinds, and is a satisfactory coating, it is said, for ships' sides, and may also be used on galvanised iron.

Graphite Paint.

The best and longest records of satisfactory protection against corrosion are said to be held by graphite paints containing silica in intimate admixture with tough crystalline foliated graphite.

An example of this is the 'Foliac' Silica-Graphite Paint manufactured by *Graphite Products, Ltd., Battersea*, which is British manufactured throughout, and has been specified for a large number of steel structures, including Admiralty airship sheds, oil fuel tanks, gas holders, decks, bridges, station roofs, railway wagons, &c.

The relative covering power of foliated silica graphite paint is very high, and owing to the lubricating properties of the pigment the speed of application to the surface is very much more rapid than with other linseed oil paints. Owing to the large adhesion surface between the vehicle and the foliated graphite a very flexible tough paint is obtained which stands wearing action due to dust, for example, much better than paints which become brittle on drying. The resistance of the pigment to the action of the atmosphere found in industrial districts is due, of course, to the fact that it is chemically inert.

Bituminous Paints.

Bituminous paint is a good preventive to rust as it adheres closely to the material to be protected, it is strongly resistant to sulphurous vapours prevalent in the air of industrial centres, and very few of the mineral acids attack it, with the exception of nitric acid. Nitrous fumes have little or no action on the better bituminous paints. A good bituminous paint should dry within four or five hours, and the chances of injury by rain or similar eventualities during the setting are, therefore, correspondingly small. A high-class bituminous paint may be applied at a cost of something like a farthing per square foot with two coats of the paint applied. The life of a well-compounded bituminous paint extends up to twenty years' efficient protection.

Luminous Paint.

Mix 50 parts of lime with 20 parts of flowers of sulphur, heat them together in a closed crucible until all fumes cease to be evolved. When quite cold grind the product up with varnish or paint which is quite free from lead. Luminous paint produced from oyster shells is the most efficient in retaining its luminosity after dark. Take clean shells and, after washing them in warm water, place them in the fire for half an hour, and when cool, after removal, pound them up very small and fine, taking away any grey portions as being of no use, then put this powder in a crucible with alternate layers of flowers of sulphur, place on the lid and cement it round with sand made

CARSON'S
ENGINEERS' PAINTS

ANTI-CORROSION

The most durable paint for Bridges and all exposed constructional ironwork.

FERRI-SILICON

A specially manufactured preservative for use on Gasometers, etc.

Unaffected by Sulphuretted Hydrogen Gas and Sulphide of Ammonia.

QUICK-DRYING ENGINEERS'

A good preservative, specially suitable for use in Foundries, Collieries, etc. Dries hard in from two to three hours.

Particulars of further specialities and address overleaf.

F. 2628

'MURALINE'

THE PERFECT WATER PAINT. Sanitary, Artistic and Durable. Requires only the addition of water to make ready for use. In 40 shades. Sold in a dry powder.

'MURAPRIME'

THE PRIMING for MURALINE and all washable water paints and distempers. Also for use over wall-paper to fix colours before applying distemper, and to prevent absorption.

'COVERINE'

THE CELEBRATED WHITE UNDERCOATING.

One coat transforms black into white.
Can be second coated in a few hours.

USE CARSON'S PURE PAINTS

Full particulars on application to—

WALTER CARSON & SONS,
BATTERSEA, LONDON, S.W. 11.

Telephone No.: Battersea 1630 (2 lines).
And at Bachelors' Walk, DUBLIN.

IMPLEMENT PAINT

Specially manufactured for the Preservation and Decoration of all Garden and Farm implements.

METALLIC PAINT

Specially manufactured for use on Radiators and all interior metal work.

F. 2629

into a stiff paste with beer; as soon as this is dry, place the crucible in the fire and bake for one hour. Wait until quite cold before opening the lid. The product should be white; any grey portions must be separated as non-luminous. Sift it through fine muslin, and mix with either varnish or gum water. For use with buoys or in places exposed to the weather, varnish of the best quality only must be used.

LACQUERS AND BRONZES.

Lacquer for Iron and Steel.

Mastic, 10 parts; camphor, 5 parts; sandarach, 15 parts; elemi, 5 parts. Dissolve in alcohol and apply without heat.

A Rustless Coating for Steel.

A solution of white wax in benzine applied with a camel-hair brush. When the film of wax hardens, the bulk of it is wiped off with a chamois leather, just sufficient remaining to prevent rust, but not to be noticeable.

Angus Smith's Coating for Pipes.

Coal Tar 1 cwt., Tallow 7 lbs., Quick Lime (slaked) 10 lbs., Pine Resin 4 lbs., Coal Naphtha, sufficient to thin the composition to a degree suitable for proper coating. Heat mixture, and immerse pipes, and allow to remain until the same temperature is diffused through the mass; then withdraw pipes. This treatment leaves a very firm and hard coating of pitch. It is very essential that the mixture be heated to a proper degree, viz., 350° to 450° F. If heated too much the pitch will not adhere properly, but will scale off.

Bronzing Liquids.

(1.)

Sulphate of copper, 1 oz.; sweet spirits of nitre, 1 oz.; water, 1 pint.

(2.)

Solution of chloride of platinum, laid on surface with a feather. When dry, blacklead over with an ordinary blacklead brush, and then lacquer.

(3.)

Boil 1 oz. of ammonium carbonate and a like quantity of blue vitriol in 1½ pint of vinegar until the latter is nearly evaporated. Then add 1½ pint of vinegar in which has been dissolved ½ drachm of oxalic acid and a like quantity of sal ammoniac. Place the mixture (known as Walker's Chemical Bronze) over the fire until it commences to boil, then allow it to cool; filter, and put by in well-closed bottles.

If a medal, etc., is to be bronzed, it is first thoroughly cleansed, then heated, and the liquid applied by means of a badger-hair brush. In a short time boiling water is poured over the medal, and when dry it is rubbed with a cotton rag dipped in oil, and then with dry cotton.

Browning for Gun Barrels.

Tincture of muriate of iron, 1 oz.; nitric ether, 1 oz.; sulphate of copper, 4 scruples; rain-water, 1 pint. When the barrel is finished let it remain in lime-water for a short time; then scratchbrush and apply bronzing.

Lacquer for Gun Barrels after Browning.

Shellac, 1 oz.; dragon's blood, ½ oz.; rectified spirit, 1 quart. Dissolve and filter.

To Chemically Blacken Brass.

Dissolve copper in nitric acid (out of doors) until all action ceases; when cold decant into another jar.

Sand-blast work, or clean in hot lye and soda; dry in sawdust; heat to 212° F.; immerse in the (cold) nitrate solution; remove and heat again sufficiently to dry off solution and burn off green colour; repeat if necessary; cool and free from oxide by brushing; dip in ammonia; rub dry with soft cloth or in sawdust—work is then brown. To make it dead black, heat just enough not to burn hands, and rub with soft leather and fine olive oil; heat, to dry oil.

Highly-polished work, if well cleaned and dipped in commercial ammonia before applying nitrate, will take a permanent black.

Sand-blasted work takes a black that cannot be removed by ordinary wear.

Black-bronzing Aluminium.

(1) Immerse the articles, after being thoroughly cleaned, in a hot solution containing 8 oz. of white arsenic, 8 oz. of iron sulphate, ¾ gallon of hydrochloric acid, and ¾ gallon of water. When sufficiently blackened the articles are removed, washed and lacquered. A more adhesive deposit may be obtained by adding to the solution a small quantity of ammonium molybdate and yellow prussiate of potash. (2) Paint the articles with a solution made by dissolving 60 grammes of

copper chloride in 300 c.c. of water and add ammonia in excess to re-dissolve the precipitate first formed. Then heat the articles, care being taken not to melt the aluminium. A deeper black may be got by repeating the process, or by dipping the articles in a solution of sodium sulphide.

Black Finish on Steel Shears, etc.

Prepare a saturated solution of caustic soda and add about ¼ lb. of saltpetre to a five-gallon solution. Boil the solution for a short time, and allow it to cool. The clear liquid should only be used, and this should be brought to the boiling point in an iron kettle. The articles should be wired as for plating and immersed in the solution. The articles will take on a grey colour at once with black underneath, and should be left in the solution until the grey finish disappears and a beautiful black remains. Rinse the articles in cold water, dry in sawdust, oil with linseed oil, and wipe clean. The resulting finish will be a fine blue-black that wears well.

VARNISHES.

Incombustible Varnish for Wood.

An application of a solution of equal parts of alum and isinglass to the place exposed to the flame prevents ignition, but not the transmission of heat. By coating wooden vessels with this varnish fluids may be boiled in them over an ordinary fire.

Varnish for Wood not acted upon by Boiling Water.

Boil in an untinned copper boiler 750 parts of linseed oil. Suspend in this, in a bag which must not touch the bottom, 150 parts of litharge and 90 parts of pulverised minium. Let the oil boil until it has assumed a dark brown colour; then remove the bag, and replace it by one containing 7 to 8 bulbs of garlic. Now melt 500 parts of pulverised amber in 60 parts of linseed oil over a strong fire; add it while boiling to the prepared linseed oil, and let it boil for 2 to 3 minutes longer, stirring it vigorously. Then take it from the fire, allow it to settle, pour off the clear liquid, and when cold put it in bottles, which should be hermetically closed.

Quick-drying Varnish.

A quick-drying varnish that is less liable to crack than that made from kauri gum is made in the United States from the nuts of the Chinese wood oil tree (*Aleurites fordii*). The tung (or wood) oil has also been found of special value for waterproofing cement.

Varnish to prebent India-rubber Gas-tubing from Leaking.

Treacle, 1½ part; gum arabic, 2 parts; white wine, 7 parts; strong alcohol, 3½ parts.

Waterproofing Material.

A new French material for waterproofing leather, cloth, paper, and other materials, consists of a mixture of eight parts of amylacetate and four of castor oil, with one part of sulphur chloride stirred into it. This forms a jelly, giving off hydrochloric acid; it liquefies after being kept tightly covered a few days, and, the acid being then neutralised with barium carbonate, gives a colourless solution on filtering. To make a varnish, nitrocellulose is dissolved in the liquid after the addition of alcohol or benzine.

CEMENTS AND GLUES.

CEMENTS.

Rust Joint.

Quick-setting.

1 lb. sal ammoniac in powder; 2 lbs. flowers of sulphur; 80 lbs. iron filings or borings. Mix to a paste with water.

Slow-setting.

2 lbs. sal ammoniac in powder; 1 lb. flowers of sulphur; 200 lbs. iron filings or borings. Mix to a paste with water. This cement is better than the quick-setting, if the joint is not required for immediate use.

For Steam Boilers, Steam Pipes, etc.

(1.)

Soft.

Red or white lead in oil, 4 parts; iron borings, 2 to 3 parts.

(2.)

Hard.

Iron borings and salt water, and a small quantity of sal ammoniac with fresh water.

(3.)

5 lbs. Paris white, 5 lbs. yellow ochre, 10 lbs. litharge, 5 lbs. red lead, 4 lbs. black oxide of manganese. The whole is to be well mixed, and a little asbestos and boiled oil added. This soon becomes nearly as hard as the iron itself.

This cement is also excellent for making fluid-pressure joints.

(4.)

Take white lead ground in oil, and add dry red lead sufficient to make a stiff putty. Pound this on a block of iron or stone until it becomes soft, continuing to add red lead until the mass will no longer soften or stick to the fingers. Interpose this putty between the flanges of the steam-pipe joints. This will make the best joint known.

FOR LEAKY IRON PIPES.

In cases where caulking, plugging, or other mechanical means of stopping leaks in iron pipes cannot be adopted, a cement made by mixing finely pulverised black manganese oxide and raw linseed oil into a thick paste will usually be found effective. It should be thoroughly forced into the leak, and the pipe should be kept warm enough to absorb or remove the oil from the manganese. In about twenty-four hours the cement should be as hard as the iron, and should adhere thoroughly, so that leakage does not again occur.

FIRE-RESISTING CEMENT FOR IRON PIPES.

Iron filings, 10 parts; brick clay, 20 parts; China clay or fireclay, 15 parts; common salt solution, 8 parts.

FOR IRON STOVE-PIPES AND FOR FILLING CRACKS IN STOVES.

Pulverised brick clay, 1 part; wood ashes, 1 part. Add a little salt, and mix to consistence of syrup.

TO FASTEN IRON TO IRON.

(1.)

Sulphur, 6 parts; white lead, 6 parts; borax, 1 part. When composition is to be applied, wet with strong sulphuric acid and smear on surfaces, which must be at once pressed together. Allow one week to dry.

(2.)

Equal parts of litharge, red lead, and sufficient glycerine to form a paste. This cement is said to be waterproof, fireproof, and to resist the action of alkalies.

FOR HOLES IN CASTINGS.

Flowers of sulphur, 1 part; sal-ammoniac, 2 parts; iron filings or borings, 80 parts. Mix to a thick paste with water.

TO FASTEN IRON TO STONE.

(1.)

Iron filings, 20 parts; plaster of Paris, 50 parts; sal ammoniac, 3 parts. Mix to a thin paste with weak vinegar.

(2.)

Sulphur, 1 part; pitch, 1 part.

TO FASTEN IRON TO MARBLE.

A cement for making repairs on switchboards when iron or other metal has to be fastened to marble may be made from thirty parts plaster of Paris, ten parts iron filings, and half-part sal ammoniac. These, states the *American Machinist*, are mixed with acetic acid to form a thin paste. This cement must always be used immediately after being mixed.

TO FASTEN METAL TO WOOD.

In order to fasten metal to wood without the use of nails or screws, the metal parts may be roughened by the use of dilute sulphuric acid. As soon as the metal has been wiped dry, it is glued on with the best joiner's glue to which a little glycerine has been added. This process is not only adapted for small plates or slabs, but also larger ones, but care must be taken that they touch the roughened wood surface evenly throughout.

CEMENT FOR FASTENING METAL LETTERS UPON GLASS, MARBLE, WOOD, ETC.

(1.)

Copal varnish, 15 parts; linseed-oil varnish, 5 parts; oil of turpentine, 5 parts; glue, 5 parts. The glue is dissolved by placing the mixture in a water-bath. When the solution is complete 10 parts of slaked lime are added to it.

(2)

A good cement for brass and glass can be made by mixing together 2 parts litharge, 1 part white lead, 3 parts linseed oil, and 1 part gum copal. Use at once.

A Strong General Cement.

4 ozs. clear gum arabic, 3 ozs. fine starch, 2 ozs. white sugar. Dissolve gum in water; then dissolve starch and sugar in gum solution; boil mixture in a water-bath until starch becomes clear. Add a few drops of oil of cloves.

To fix Paper to Metals.

Gum tragacanth, 30 grammes; gum acacia, 120 grammes; water, 500 cubic centimetres. Dissolve, filter, and add 2½ grammes of thymol in 120 cubic centimetres of glycerine. Add water to make up bulk of 1 litre.

To fix Cloth to Metal or Wood Rollers.

Glue, 1 part; isinglass, 1 part. Soak in small quantity of water for 10 or 12 hours. Then boil, and add pure tannin till it becomes thick. Apply hot.

To fasten Leather to Metal.

Digest one part of coarsely crushed gall-nuts with eight parts of distilled water about six hours, and filter through linen. Then pour one part of cold water over one part of glue, leave it to stand for twenty-four hours, and heat the whole, whereby a concentrated glue solution is obtained. Now coat the leather with the warm gall-nut extract, bring the glue solution on the roughened and warm metal, lay the leather on it, press it firmly, and allow it to dry in the air. The leather will adhere so firmly to the metal that it cannot be separated without tearing it.

To cement Leather on Iron Pulleys.

Roughen pulley with old file. Glue leather to pulley with glue, 1 part; glycerine, 1 part.

To cement Rubber upon Metal.

Soak pulverised shellac in 10 times its weight of strong ammonia. The result will be a transparent mass, which becomes liquid in 3 to 4 weeks without the use of water. This fluid makes the rubber soft, but after the evaporation of the ammonia it becomes hard, and impermeable to gases and fluids.

To join Leather Driving-Belts.

Mix 10 parts of bisulphide of carbon and 1 of oil of turpentine, and dissolve in it a sufficient quantity of gutta-percha to form a paste. The pieces of leather to be joined are cleansed from oil and grease by laying a rag upon their surfaces and placing a hot iron upon it. Both pieces are then spread with the cement, and subjected to pressure until the cement has become dry.

To cement Leather to Leather.

Soak ordinary glue or isinglass for 12 hours in sufficient cold water to cover it. Boil, and add pure tannin until the solution becomes sticky and has the appearance of white of egg.

Cement for mending Rubber Goods.

Bisulphide of carbon, 26 parts; gutta-percha, 2 parts; caoutchouc, 4 parts; fish glue, 1 part.

Cement for Mending Celluloid and Hard Rubber.

(1.)

For celluloid goods prepare a cement made by dissolving one part of camphor in four parts of alcohol, and adding an equal amount of shellac to the camphor solution. The cement must be applied hot. For hard rubber articles use a melted mixture of gutta-percha and genuine asphalt, which is likewise applied hot. The celluloid as well as the hard rubber goods must have the fractured surfaces kept pressed together until the cement has cooled.

(2).

For cementing celluloid, dissolve celluloid in amylacetate to make a thick jelly. This cement may be used cold. It can also be used to cement china, silk or cotton fabrics, leather, etc.; it is absolutely waterproof. A piece of paper smeared with the jelly makes an excellent sticking-plaster. (H. R. K.)

To Cement Wood to Tin.

1 part yellow wax melted: stir in 2 parts gutta percha chips until quite dissolved, then dissolve therein 2 parts shellac and $\frac{1}{10}$th part boiled linseed oil. Apply melted cement to dried surface of wood and tin, and press two surfaces together for 24 hours.

Cement for quickly closing Leaky Places in Barrels.

Tallow, 25 parts; wax, 20 parts; lard, 40 parts; sifted wood ashes, 25 parts. Mix together by heating, and apply to the defective place by means of a heated knife-blade.

Cutler's Cements for fastening the Blades of Knives into Handles.

1. Rosin, 4 parts; beeswax, 1 part; brick dust, 1 part.
2. Rosin, 4 parts; pitch, 4 parts; tallow, 2 parts; brick dust, 2 parts.

Cement for Marble.

Four parts finely-powdered gypsum; 1 part finely-powdered gum arabic. Mix intimately, then with a cold solution of borax make into a mortar-like paste. Use the paste as a cement. Leave the cemented parts for several days undisturbed so that the cement shall thoroughly set.

Cement for Glass.

15 parts caoutchouc in 60 parts chloroform; add about 35 parts mastic, and allow to stand without heat for eight days.

Cement is elastic and transparent; additional caoutchouc increases elasticity.

Oil Resisting Cement.

For use in certain engineering work a cement is often required which will withstand the action of paraffin or petroleum jelly. Recent investigations show that this can be made by boiling rosin with one-third its weight in caustic soda and one and two-thirds its weight of water. After cooling the water separates and can be thrown away, the residue being then made into a plastic state with plaster of Paris. It is said that a joint made with this will stand any ordinary conditions.

Plastic Cements.*

(*J. B. Barnitt.*)

Asphalt and Pitch.

Asphalt in benzol is useful as an adhesive for uniting glass for photographic and microscopical uses, also for coating wood, concrete, brick work, steel, etc., where the melted asphalt would be too thick to apply readily. Benzol is the cheapest and most satisfactory solvent. For waterproofing, melted asphalt with a small amount of paraffin added and in particular cases boiled oil, is used :—

(*a*) Refined lake asphalt.

(*b*) Asphalt, 4 parts; paraffin, 1 part.

(*c*) Asphalt, 10 parts; paraffin, 2 parts; boiled oil, 1 part.

Any of the above may be thinned with hot benzol or toluol.

(*d*) Pitch, 8 parts; resin, 6 parts; wax, 1 part; plaster, $\frac{1}{2}$ to $\frac{1}{2}$ part.

(*e*) Pitch, 8 parts; resin, 7 parts; sulphur, 2 parts; stone-powder, 1 part.

Compositions (*d*) and (*e*) are used to unite slate slabs and stoneware for engineering and chemical purposes.

The following are plastic cements for caulking :—

(*f*) Pitch, 3 parts; shellac, 2 parts; pure crude rubber, 1 part.

(*g*) Pitch, 1 part; shellac, 1 part; rubber substitute, 1 part.

(*f*) and (*g*) are mixed by melting over a burner.

Resin, Shellac, and Wax.

A strong stone cement having little body and applied in layers.

(*a*) Resin, 8 parts; wax, 1 part; turpentine, 1 part. For nitric and hydrochloric acid vapours.

(*b*) Resin, 1 part; sulphur, 1 part; fireclay, 2 parts. Sulphur gives great hardness and permanency in resin cements.

Good waterproofing cements are :—

(*c*) Resin, 1 part; wax, 1 part; powdered stone, 2 parts.

(*d*) Shellac, 5 parts; wax, 1 part; turpentine, 1 part; chalk, 8 to 10 parts.

For a soft airtight paste for ground glass surfaces :—

(*e*) Wax, 1 part; vaseline, 1 part.

A strong cement without body for metals (not copper), porcelain and glass.

(*f*) Powdered shellac, 1 part; ammonia water, 10 parts. Allow to stand until solution is effected.

Rubber.

As a leather cement :—

(*a*) Asphalt, 1 part; resin, 1 part; gutta percha, 4 parts; carbon disulphide, 20 parts.

As a resistant to acid vapours :—

(*b*) Rubber, 1 part; linseed oil, 2 parts; fireclay, 3 parts.

A plain rubber cement :—

(*c*) Cut crude rubber in small pieces and then add carbon disulphide or benzol, allowing the rubber to dissolve.

Corks and wood are made impervious to water by soaking them in the above solution.

* *The General Chemical Bulletin*, Laurel Hill Laboratory, Feb. 1917.

Linseed Oil.

For aqueous vapours :—

(*a*) China clay and linseed oil.

(*b*) Lime and linseed oil, forming the well-known putty.

(*c*) Red or white lead and linseed oil.

The above mixtures become very strong when set, and are best diluted with powdered glass clay, or graphite.

(*d*) Oxide of iron and linseed oil.

Casein, Albumen, and Glue.

Cements of this nature are resistant to moderate heat and oil vapours but not to acid fumes.

(*a*) Finely-powdered casein, 12 parts; fresh slaked lime, 50 parts; fine sand, 50 parts; and enough water to make a thick mass.

A strong cement for ground unions standing a moderate heat.

(*b*) Casein in fine powder, 1 part; rubbed with silicate of soda, 3 parts.

(*c*) White of egg made into a paste with slaked lime. This should be used immediately after being made up.

A composition for soaking corks, wood packing, etc., to render impervious to oil vapours :—

(*d*) Gelatine, 2 parts; glycerine, 1 part; water, 6 parts.

Silicate and Oxychloride Cements.

For oil vapours standing highest heat :—

(*a*) Paste of sodium silicate and asbestos.

For gaskets for superheated steam retorts, furnaces, etc. :—

(*b*) Sodium silicate and glass.

(*c*) Sodium silicate, 50 parts; asbestos, 15 parts; slaked lime, 10 parts.

A metal cement :—

(*d*) Sodium silicate, 1 part; oxides of zinc, lead, or iron, singly or mixed, 1 part.

(*e*) Zinc oxide, 2 parts; zinc chloride, 1 part; water to make a paste.

(*f*) Magnesium oxide, 2 parts; magnesium chloride, 1 part; water to make a paste.

Flour and Starch.

(*a*) Flaxseed makes a very tough cement, but does not withstand water.

(*b*) Flour and molasses to a stiff paste.

A permanent cement for ordinary temperatures, impervious, but attacked by condensing steam and nitric vapours.

(*c*) Stiff flour paste and concentrated zinc chloride solution.

As a core compound :—

(*d*) Dextrine and fine sand.

Miscellaneous.

For insertion of glass tubes in brass or iron :—

(*a*) Litharge and glycerine mixed to a stiff paste.

For high heat :—

(*b*) Alumina, 1 part; sand, 4 parts; slaked lime, 1 part; borax, ½ part; water.

Core compounds :—

(*a*) Dextrine, 1 part; sand, 10 parts; water to form a thick paste.

(*b*) Anthracite coal powdered with molasses added to thick paste.

(*c*) Resin, partly saponified by soda lye, 1 part; flour, 2 parts; sand, 4 parts; with water as a diluent.

(*d*) Powdered glue, 1 part; flour, 4 parts; sand, 6 parts; water.

As a coating for glass ware to protect from injury by direct flame :—

(*a*) A mixture of fireclay and plumbago made into a paste with water.

For retorts :—

(*a*) Fine flour and lime, 1 part; potters' earth, ½ part; make a moist paste with white of egg well beaten with a little water.

For melting pots :—

(*b*) Sift brickdust and mix with equal quantity of red lead; rub together with boiled linseed oil, which has been mixed with sand to a stiffness of cement. In covering dishes apply the paste first, then apply sand and heat.

(*c*) Put freshly slaked lime with concentrated solution of borax, apply with a stiff brush and allow to dry. Upon heating a fused glaze is obtained.

For large pots :—

(*d*) Litharge, 6 parts; fresh burnt lime, 4 parts; white bole, 2 parts; and mix with cold linseed oil.

GLUES.

Preparation and Use of Glue.

Commercial glue is furnished in a cake form, in flakes, or pulverised; it should be kept in a dry place so that it will not mould. No matter what the form of the glue is, it should be soaked in cold water for several hours before it is heated. The water used for this purpose ought to be distilled; the drip from steam radiators may be utilised, if desired. The use of distilled water guards against chemical action due to impurities in the water, which may contain sulphur, lime, or iron, all of which are injurious to glue. If glue is soaked in hot water, it quickly decomposes and its strength is impaired. The amount of water required should be stated by the makers.

Glue cake, ¼ to ½ in. thick, requires about twelve hours to dissolve; it should be broken into small pieces before being put to soak. Flake glue requires from six to eight hours, according to the thickness of the flake. Pulverised glue may be dissolved in from three to three and a half hours. The soaking process should not be hurried.

Glue should not be heated until it has been absolutely dissolved by soaking in cold water. After being heated, the glue may be diluted with hot water to obtain the required consistency. Glue should never be heated sufficiently to make it boil. It is also bad practice to prepare large quantities of glue at a time, because it loses its strength rapidly after being under heat for about four hours.

A satisfactory glue-heater should have ample accommodations for all the glue that will be prepared at one time, say, six or more glue kettles. The kettles in which the glue is heated should be made of aluminium, and their size and number should provide for handling glue of various consistencies in sufficient quantities to last not more than four hours. Aluminium is the most suitable metal for glue pots, because the scum on the glue does not adhere to the inside of the pots, so that they are easily cleaned.

A thermometer should be part of the equipment of a glue-heater, for the temperature at the bottom of a pot 6 ins. deep should not be over 150° F., which will bring the temperaure at the top to about 140° F. Higher temperatures than this destroy the adhesive power of glue. The pots should be thoroughly cleaned at least once each day. The glue that has become cooled should never be reheated, as reheated glue loses about 50 per cent. of its strength. It is good practice to have a new lot of glue ready for use before the glue already prepared is consumed. ('*Machinery*,' *Oct.* 12, 1922.)

Waterproof Glues.

(1.)

A very cheap waterproof glue is made by melting common glue with the smallest quantity of water possible. Add to this, by degrees, linseed oil made 'drying' by boiling it with litharge. While the oil is added the ingredients must be well stirred so as to mix them thoroughly. Another plan: Take of a very thick solution of glue ten parts, linseed oil varnish five parts, and litharge one part. Boil these together for ten minutes, and use while hot. The additional ingredients have no effect whatever on the adhesive properties of the glue, which is rendered entirely waterproof.

(2.)

Gum shellac 3 parts and india-rubber 1 part by weight, these constituents being dissolved in separate vessels in ether, free from alcohol, subject to a gentle heat. When thoroughly dissolved, the two solutions are mixed, and kept for some time in a vessel tightly sealed. This glue resists the action of water, both hot and cold, as well as most acids and alkalis. If the glue is thinned by the admixture of ether, and applied as a varnish to leather along the seams where this has been sewn together, it renders the joint or seam water-tight, and almost impossible to separate.

Fire-Resisting Glue.

Mix four parts linseed oil and one part quicklime, then boil slowly until a paste. Spread the mixture on a plate and dry in the open air. It will become very hard, but can be dissolved over a fire, or in a gluepot like common glue. This composition really is not glue at all, but a sort of waterproof cement that is extremely tenacious.

Liquid Glues.

(1.)

1 part glue, 1 part water, 1 part vinegar. Dissolve by gentle heat, and then add 1 part alcohol.

(2.)

White glue, 16 ozs.; dry white lead, 4 ozs.; rain-water, 2 pints. Dissolve by gentle heat, and then add alcohol, 4 ozs.

(3.)

Clear gelatine, 100 parts; glue, 100 parts; alcohol, 25 parts; alum, 6 parts. Mix whole with 200 parts of 20 per cent. acetic acid, and heat in water-bath for 6 hours.

Marine Glues.

(1.)

India-rubber, 4 parts; coal-tar naphtha, 34 parts; powdered shellac, 64 parts.

(2.)

Glue, 12 parts; dissolve in water; add yellow resin, 3 parts. When dissolved, add turpentine 4 parts. This glue is inferior in quality to (1).

Strong Glue.

Add a little powdered chalk to common glue, and mix thoroughly.

Glue for Parchment.

Parchment shavings, 1 lb.; water, 6 quarts. Boil until dissolved, then strain, and evaporate to consistency of ordinary glue.

Rice Glue.

Rice, flour, and water. Mix together cold, and then boil, stirring all the time.

Casein Glue.

Casein glue is exceedingly resistant to the action of water and retains a very high percentage of its original strength even after long immersion under water. Unless properly compounded casein glue deteriorates if kept. The 'First Report of the Adhesive Research Committee, 1922' (published by His Majesty's Stationery Office, Imperial House, Kingsway, London, W.C. 2; price 4*s.* net), gives the following as satisfactory:—

Casein, 78 per cent.; dry sodium carbonate, 4·5 per cent.; sodium fluoride, 4·0 per cent.; freshly slaked lime, 12·5 per cent.; sodium arsenate, 1·0 per cent. All ingredients must be ground to pass through a 90-mesh sieve.

For use, mix the cement with water; if mixed with a weak solution of gelatin glue the strength will be about 10 per cent. greater. Average breaking stress, about 1,000 lbs. per sq. in.

PASTE.

Water 1 quart, alum $\frac{3}{4}$ oz. Dissolve, and when cold add flour to make it the consistence of cream, then bring it to a boil, stirring it all the while, then add a teaspoonful of powdered resin, and also a few drops of oil of cloves. This paste will not turn sour by keeping.

PLASTERS.

Plaster of Paris.

Intimately mix 4 per cent. of powdered marsh mallow root and knead to a dough with 40 per cent. of water. The mass will harden in about one hour, and can be cut, filed, turned, or drilled. Eight per cent. of marsh mallow renders it still tougher.

Hardening Plaster.

Plaster of Paris articles may be hardened to an extent not previously accomplished by means of a solution of borate of ammonia (ammonium borate). This compound, according to the *Metal Record*, is made by dissolving boracic acid in hot water, and then adding ammonia water to it until the solution turns red litmus paper blue (or so that the solution smells faintly of ammonia). The solution must not smell too strongly of ammonia, and the best results are obtained when very little free ammonia is present. The borate of ammonia may be applied to the plaster of Paris article after it has been cast or before mixing. The most satisfactory method is to treat the cast itself. The solution of borate of ammonia is applied to the dry plaster object and the absorption allowed to take place. The surface gradually hardens, and finally the interior. The plaster so hardened may be employed for a large number of uses. Instead of having the soft nature of ordinary plaster it resembles brick or stone.

Hardening-Plaster for Floors.

The following process for hardening plaster so that it may be used for flooring, as wood and tile are at present, comes from France. About 6 parts of good-quality plaster are intimately mixed with 1 part of freshly slaked white lime finely sifted. This mixture is then laid down as quickly as possible, care being taken that the trowel is not used on it for too long a time. The floor should then be allowed to become very dry, and afterwards be thoroughly saturated with sulphate of iron or zinc—the iron giving the strongest surface, the resistance to breaking being twenty times the strength of ordinary plaster. With sulphate of zinc the floor remains white, but when iron is used it becomes the colour of rusted iron; but if linseed oil, boiled with litharge, be applied to the surface, it becomes of a beautiful mahogany colour; this is especially the case if a coat of copal varnish be added.

LUBRICANTS AND OILS.*

Greases for Railway Axles.

(1.)

Water, 1 gallon; palm oil, 6 lbs.; clean tallow, 3 lbs.: common soda, ½ lb.

(2.)

Tallow, 8 lbs.; palm oil, 10 lbs. Heat to 212° F., and well stir.

Antifriction Grease.

(1.)

Tallow, 100 lbs.; palm oil, 70 lbs. Boil together, and when cooled to 80° F. strain through a sieve and mix with 28 lbs. common soda and 1½ gallon of water.

(2.)

Blacklead, 1 part; lard, 4 parts.

Rosin-Oil Soap.

90 lbs. powdered slaked lime, stirred into 100 lbs. rosin oil. Heat the mixture, constantly stirring it well until a uniform paste of the consistence of syrup is obtained. This rosin oil is a component of all the patent wagon greases.

Blue Patent Grease.

2 lbs. powdered slaked lime, heated in 550 lbs. of crude rosin oil for 1 hour, and then allowed to cool. Skim the oil, and stir in 10 to 12 lbs. of rosin-oil soap, until the compound is of a butter consistency and of a blue colour.

Yellow Patent Grease.

1 part turpentine, 20 parts caustic lye. Add to 350 parts of blue grease.

Black Patent Grease.

2 parts lampblack, 110 parts blue grease.

Patent Palm-Oil Wagon Grease.

Melt 10 lbs. rosin-oil soap in 10 lbs. palm oil: add 550 lbs. rosin oil, with as much rosin-oil soap as will give the whole the consistence of butter; finally, add 7¾ to 10 lbs. of caustic soda lye.

Adhesive Grease for Machine Belts.

Lubricate the belts with fish oil to which 10 per cent. of tallow has been added. This will make them flexible, and augment their friction on the pulleys.

Grease for Waterproofing Leather.

Oleic acid, 24 parts; crude stearic acid, 6 parts; ammoniacal soap, 18 parts; extract of tannin, 6 parts; water, 24 parts. Melt the oleic acid together with the stearic acid; then add gradually the ammoniacal soap, the extract of tannin, and finally the water. The ammoniacal soap is obtained by adding to heated oleic acid caustic ammonia until, after continued stirring, the odour of ammonia remains apparent and the whole congeals to a jelly-like mass.

Cooling Compound for Hot Bearings.

(1.)

Mercurial ointment mixed with black cylinder oil and applied every quarter of an hour, or as often as expedient. The following is also recommended as a good cooling compound for heavy bearings:—Tallow, 2 lbs.; plumbago, 6 ozs.; sugar of lead, 4 ozs. Melt the tallow with gentle heat, and add the other ingredients, stirring until cold. For lubricating gearing, wooden cogs, etc., nothing better need be used than a thin mixture of soft soap and black lead.

(2.)

For cooling a hot bearing Professor Lecocq, of the Charleroi Higher Industrial School, recommends that the oil usually employed for lubrication be dissolved in an equal quantity of petroleum spirit, the evaporation of which latter will, he says, afford the cooling desired.

---

* See also pages 1021–1034.

Watchmaker's Oil.

Expose the best olive oil to a temperature a few degrees below the freezing point, which will cause all foreign substances to separate. Pour off carefully the supernatant clear oil, and filter through a cup of linden wood or pith of elder wood. By this process an oil is obtained which will remain liquid for several years, and does not attack the delicate machinery.

Neat's-foot oil treated in the above manner furnishes a less useful oil, since it loses much fatty matter by exposure to cold.

A very useful oil is obtained by dissolving 1 part of pure neat's-foot oil in 3 of pure benzine. Allow the compound to remain for several days in a closed vessel; then filter, and expose the solution to a temperature of 40° F., at which it is again filtered, and the benzine distilled off. The oil should be kept in small, dark vials protected from the air.

A very fine lubricant for clocks and watches is, according to Artemus, obtained by mixing 2 parts of solar oil with 1 of rape-seed oil.

To test the fitness of Oils for Lubricating Watches and Clocks.

Pour a drop of the oil to be tested upon different metal plates, as iron, brass, tin, lead, etc.; keep them in a place free from dust, and examine the drops during 8 to 14 days in regard to their liquidity. Oil remaining liquid after the lapse of this time can be safely used.

Viscosity of Various Standard Oils.

Description.	Viscosity.	
	At 70° F.	At 120° F.
Sperm oil	100	45
Whale oil	190	70
Olive oil	213	75
Lard oil	225	78
Neatsfoot oil	247	80
Rape-seed oil	250	88
Axle oil	600	120
Valve oil	—	550
Cylinder oil	—	700

In the above table sperm oil is taken as the standard for viscosity at 70° F.

The viscosity of thick oils can be greatly reduced by adding 8 per cent. of naphthalene to the oil.

An objectionable characteristic in an oil is its tendency to become resinous with use, due to the oil undergoing the process of oxidation. This change in the oil indicates, to some extent, the degree of refining process the oil has undergone. A simple test can be made in the following way:—Place a small quantity of oil in a glass beaker and put in a nearly equal amount of nitric acid. Should the oil have no tendency to gum, the acid and oil will combine and get very thick, while should there be any objectionable characteristic the oil will remain thin.

CLEANING AND PRESERVATIVE COMPOSITIONS.

To clean Brass.

Oxalic acid, 1 oz.; Rotten stone, 6 oz.; powdered gum arabic, ½ oz.; sweet oil, 1 oz. Rub on with piece of rag.

Soap for cleaning Metal-work.

The soaps used for cleaning metal-work usually consist of mixtures of vaseline, oleic acid, and fat, mixed with a small quantity of rouge. When freshly prepared they leave nothing to be desired; but, unfortunately, such mixtures soon turn rancid and become unfit for use. A newer soap for metal-work, which is stated to be free from this objection, is made from cocoanut butter in the following way:—2·5 kilogrammes of the butter are melted in an iron vessel, together with a little water, and to the mixture is added, with constant stirring, 180 grammes of chalk, 87·5 grammes of alum, 87·5 grammes of cream of tartar, and 87·5 grammes of white lead. This mixture is then poured into moulds and allowed to solidify. The soap so obtained is made into a paste with water, rubbed over the metal to be cleaned, and finally removed by a dry rag or chamois leather.

To clean Grease from Paper.

(1.)

Warm the spotted part, and press blotting-paper upon it until all the grease is extracted that is practicable by this method; then with a brush apply very hot turpentine, and wash off with alcohol.

(2.)

Apply benzine collas freely to the spot.

To clean Marble.

Powdered chalk, 1 part; powdered pumice stone, 1 part; soda, 2 parts. Mix with water. Paint over marble; then clean, and wash off with soap and water.

To clean Grease from Stone or Marble.

Soft soap, 1 part; fuller's earth, 2 parts; potash, 1 part. Mix with boiling water. Lay it on the spots, and let it remain for a few hours.

A Solvent for Rust.

It is often very difficult, and sometimes impossible, to remove rust from articles made of iron. Those which are very thickly coated are most easily cleaned by being immersed in a solution (nearly saturated) of chloride of tin. The length of time they remain in this bath is determined by the thickness of the coating of rust. Generally twelve to twenty-four hours is long enough.

To cleanse Paint Brushes from Dried-in Paint.

Suspend the brush in a tumbler containing a solution of 1 part of crystallised sodium carbonate in 3 of water, in such a manner that it hangs several inches from the bottom of the tumbler. Let it stand from 12 to 24 hours in a moderately warm place (140° to 150° F.). The dried paint will be softened so much that it can be easily washed out with soap and water. Brushes which have become as hard as stone can be restored by this process.

To Remove Rust from Iron.

(1.)

Freely apply turpentine or paraffin oil, leave for twelve hours, and then rub with the finest emery cloth.

(2.)

Dip in strong hot potash bath, for about ½ hour. Then immerse in a cold muriatic acid pickling solution—2 parts water, 1 acid. This removes rust in a few minutes, the metal being attacked but very little. Without the potash it will take about 65 minutes against 4 when both baths are used. The appearance of the rust when treated is black and soft and it can almost be entirely rubbed off with the hands. The metal so treated has a smooth, glossy finish.

(3.)

A dip of 40 parts of muriatic acid and 60 parts of water is effective for removing rust. After the rust has been removed, it is necessary to dip the steel in a strong alkaline bath to remove every trace of acid. The alkaline solution usually employed for this purpose is composed of 2 oz. each of soda ash, sodium cyanide, and caustic lime.

To Remove Rust from Iron Electrically.

A very simple and effective way of cleaning rusted iron articles, no matter how badly they are rusted, consists in attaching a piece of ordinary zinc to the articles, and then letting them lie in water to which a little sulphuric acid is added. They should be left immersed for several days, or a week, until the rust has entirely disappeared, the time depending on how deeply they were rusted. If there is much rust, a little sulphuric acid should be added occasionally. The essential part of the process is that the zinc must be in good electrical contact with the iron; a good way is to twist an iron wire tightly around the object, and connect this with the zinc, for which a remnant of a battery zinc is suitable, as it has a binding post. Besides the simplicity of this process, it has the great advantage that the iron itself is not attacked in the least as long as the zinc is in good electrical contact with it. When there is only a little rust, a galvanised iron wire wrapped around the object will take the place of the zinc, provided the acid is not too strong. The articles will come out a dark grey or black colour, and should then be washed thoroughly and oiled. The method is specially applicable to objects with sharp corners or edges, or to files and other articles on which buffing wheels ought not to be used. The rusted iron and the zinc make a short-circuited battery, the action of which reduces the rust back to iron, this action continuing as long as any rust is left.

To keep Machinery from Rusting.

Take 1 oz. of camphor, dissolve it in 1 lb. of melted lard; mix with it (after removing the scum) as much fine blacklead as will give it an iron colour. Clean the machinery, and smear it with this mixture. After 24 hours rub clean with soft linen cloth. It is stated that this mixture will keep machinery clean for months under ordinary circumstances.

To protect Iron and Steel from Rust.

The following method is but little known, although it deserves preference over many others: Add $1\frac{3}{4}$ pints of cold water to 7 ozs. of quicklime. Let the mixture stand until the supernatant fluid is entirely clear. Then pour this off, and mix it with enough olive oil to form a thick cream, or rather to the consistency of melted and recongealed butter. Grease the articles of iron or steel with this compound, and then wrap them up in paper; or, if this cannot be done, apply the mixture somewhat more thickly.

To keep Tools from Rusting.

Half-ounce camphor dissolved in 1 lb. melted lard; skim and mix in as much black-lead as will give it an iron colour. Smear tools, and after 24 hours rub clean with soft linen cloth.

Or, 6 oz. lard to 1 oz. rosin. When semi-fluid it is ready for use.

Or, use vaseline, to which, when warm, a little powdered camphor has been added.

Removing Rust from Tools.

Tools which have become very rusty should be treated with a chemical solution, instead of trying to scour the rust off by means of emery cloth. A good solution for removing rust may be made as follows. Into one quart of distilled water dissolve, little by little, sufficient chloride of tin to obtain a saturated solution, that is, until the water will not dissolve any more of the salt. Put the tool into a receptacle containing the solution and let it stand over night. In the morning rinse the solution off in running water and dry thoroughly with a piece of chamois or cloth.

(*W. S. S.*, '*Machinery.*')

Blueing Steel.

Outfit.

The outfit consists of a cast-iron kettle, one tank for boiling water, and one tank for oil (aquiline). The mixture consists of nine parts of saltpetre, by weight, and one part pyrolusite. The articles are hung in perforated baskets. A scraper is necessary for the melting kettle to stir the solution and to scrape the sediment from the bottom.

Method.

The desired temperature for treatment is obtained when all the mixture has melted and begun to boil, and when a pinch of fine sawdust thrown in bursts into flame the moment it reaches the surface. The temperature must be kept constant to give good results. In operation, the full basket may be hung on the chain at one end of a lever and lowered into the solution. The articles are left in for three minutes, then are slowly lifted out to allow the surplus solution to drain off; they are then dipped into hot water to clean off the solution; after the water has drained off, the articles are dipped into the oil and taken out as quickly as possible and allowed to drain. It is essential to note that there be no rust on the work, and that red-hot cast iron is attacked by these chemicals.

Blueing Small Screws.

Use a boiling bath composed of:

Water	1 gallon.
Hyposulphite of soda	2 ozs.
Acetate of lead	2 „

The hyposulphite of soda and the acetate of lead are first dissolved in the water and the whole is then brought up to boiling point. The work, which must be absolutely clean and free of grease, and preferably polished, is immersed in the bath for a few seconds, and then withdrawn. At first the work will be a kind of yellow, changing to red and then to blue almost immediately. The work is rinsed in water and quickly dried. Changing the length of time during which the work is immersed in the bath will give varying depths of colour. When the desired tint is obtained, note the time immersed, and give subsequent dippings the same period in the bath.

The brilliancy of the blues obtained by the above method is greatly enhanced if the work is copper plated before immersion in the colouring bath. The plating may be accomplished by the dipping process. To a quantity of distilled water add all the copper sulphate it will dissolve, then for every four ounces of distilled water add from 10 to 14 drops of sulphuric acid. Start with 10 drops in the first instance and add more sulphuric acid if required. Before coppering it is absolutely essential that the work be free from grease. It should be noted that in all colouring processes the higher the initial polish on the work the greater the brilliance of the finished work.
(*'Machinery.'*)

Blueing Small Hardened Steel Springs Without Heating.

Thoroughly clean the springs in boiling lime water and afterwards remove any remaining lime by means of a brush. Dip the springs in a nitric acid bath; wipe clean and oil; linseed oil is generally used for this purpose. (*W. R., 'Machinery.'*)

Waterproof and Fireproof Boards.

The boards are first laid in a waterglass solution of 5° to 10° Bé., where they are left 10 to 12 hours, when they are taken out and allowed to drip off. After drying, they are placed in a solution (gravity 2° to 3° Bé.) of calcium chloride, magnesium chloride, and ammonium chloride. In this they are left four to six hours, and after dripping off and drying again, they are ready for use.

COPYING PROCESSES.

Glycerine-Jelly Process.

(1.)

8 ozs. glycerine, 2 ozs. best glue; to the glue add 8 ozs. of water, and when dissolved stir in glycerine. Pour the mixture into a zinc dish, and as soon as it sets it is ready for use. Use aniline ink.

(2.)

16 ozs. glycerine, 8 ozs. golden syrup, 3 ozs. flake gelatine, 16 ozs. water. Soak gelatine in water for 10 hours; heat gently in water bath; add glycerine and golden syrup. Pour into dish. Use aniline ink.

(3.)

Gelatine, 1 lb.; water, 2 lbs.; glycerine, 5 lbs. Melt together and pour in shell dish. For the ink: aniline violet, 1 oz.; water, 5 ozs.; methylated spirit, 1 oz.

(4.)

Whiting to fill dish; glycerine in sufficient quantity to mix the whiting to the consistency of glaziers' putty. Press into dish and smooth with knife, and finally with small indiarubber squeegee. For ink use violet aniline, ½ oz.; sugar, ½ drachm; boiling water, 2 ozs.; when cold add 1 drachm each of alcohol and glycerine and 2 drops carbolic acid.

Write or draw original on dry smooth paper with a pen well filled with the aniline ink. Directly it is quite dry place it face down for 1 to 5 minutes, according to number of copies required, on composition, the surface of which must previously be moistened with water and dried with paper (newspaper will do); gently smooth down with hand to remove air bubbles. On peeling it off a negative is left on the composition. To take copies, apply to the negative sheet after sheet of any paper, smoothing them down with slight pressure, and removing them at first as quickly as possible; but as the copies become faint the paper may be left down longer on the negative, or it may be damped before putting down. The copies having been taken, sponge off the negative immediately with cold water, or tepid water if it does not come off readily. When the surface is worn and uneven, re-melt composition; a little glycerine may have to be added at each re-melting.

(5.)

The following formula for making hectograph pads is given by Mr. H. E. Smith in the 'American Engineer and Railroad Journal': Clear hide glue, 1 lb.; water, 1¼ pint; glycerine, 2½ pints. The glue should be of a good quality, and the kind that comes in transparent, light-brown sheets, as the white or brown opaque glue does not give as good results. Break the glue into small pieces and soak it in the water over-night in a covered vessel. Then melt it in a water-bath, and add the glycerine, which should previously be heated to the same temperature as the melted glue. Stir only as much as is necessary to mix the glue and the glycerine, as too much stirring introduces air bubbles, which are difficult to remove. Pour the hot mixture through a cheese-cloth bag into the pans. When the pans are filled and the jelly is still quite fluid, sweep off air bubbles or impurities from the surface with the edge of a card. Let the pans stand 48 hours before using. This formula calls for much less water than usually required by other formulas, since it is preferred to secure the requisite softness by means of the glycerine, which does not evaporate and allow the pads to dry out and harden, as does the water.

In writing the original copy always use hard, glazed paper, and write with hectograph ink. In making the negative moisten the surface of the pad with a cold wet sponge, wiping off the excess of moisture. Dry off with a newspaper, and let it stand for two minutes. Place the original face down on the pad for from one to three minutes, rubbing down to a perfect contact, and then carefully remove. In printing apply a clean sheet of any kind of paper so that it touches the hectograph at all points, rubbing as little as possible. Never use hot water for removing the negative; as soon as the copies are all made, wash off with a sponge and cold water and dry off well with a newspaper. Never let the pad stand with ink in it after the copies are made, and always keep it closed when not in use.

Blakeley Process.

The following process, devised by Mr. R. W. Blakeley, of Pendleton, Manchester, is a modification of the glycerine-jelly process, but dispenses with the glycerine-jelly.

Take a pad of 10 to 12 sheets of tissue paper, damp well and screw up for a minute between damping sheets in the ordinary letter-copying press to distribute the moisture evenly. The pad should be thoroughly damp—if too dry it will not take up the ink from the original and if too wet the ink will run.

The original is drawn on any hard-surfaced paper with aniline ink, such as violet blue copying ink, and then placed face down on the damp tissue paper pad and screwed up in the press for five minutes; this gives the negative on the damp pad, from which copies are taken by screwing up blank sheets with the negative in the press. For the first copy 20 seconds in the press is enough. For the fifth or sixth 45 or 50 seconds is required.

As the negative pad loses moisture to every copy this damping cloth under the negative is redamped every half-dozen copies or so.

Autocopyist.

Tough paper is coated by means of a sponge, at a temperature of 120° F., with a gelatine (flake) 5 ozs.; glycerine, 5 drachms; water, 20 ozs. and then allowed to dry.

The best paper to use is either prepared vegetable tracing-paper, or else vegetable-parchment paper.

The prepared paper is stretched tightly over a felted wooden block or board. The original is written or drawn on smooth paper with an ink composed of a saturated solution of alum tinged with aniline black, and then applied to the prepared paper as in the glycerine process. An inked roller (lithographic ink) is then passed over the surface, a sheet of paper laid on the latter, and a felted roller passed briskly over two or three times, and the paper taken off. One hundred to two hundred sharp, clear copies can thus be obtained. The prepared paper cannot be cleaned and used a second time.

Cyclostyle.

A stencil is formed by writing or drawing on prepared paper with a pen fitted with a revolving perforator. Copies are taken by passing over the stencil an india-rubber scraper charged with lithographic ink thinned with lard-oil.

Blue Photographic Copying-Process.

Draw design on thin paper. Brush paper over with a solution of (1), and dry in the dark.

(1.)

Double citrate of iron and ammonia, 44 grs.; water, 1 oz.

Expose under plan, which is pressed out flat by a sheet of plate-glass, and develop with solution (2).

(2.)

Ferrocyanide of potassium, 50 grs.; water, 1 oz.

Wash with water slightly acidulated with hydrochloric acid, and then in water alone, and dry.

This gives white lines on a blue ground, or a negative of the drawing.

The following gives blue lines on a white ground, or a positive print:—

Sensitising solution—

(1.)

Ferric chloride, 50 grs.; oxalic acid, 25 grs.; water, 1 oz.

Develop with

(2.)

Ferrocyanide of potassium, 80 grs.; water, 1 oz.

All the steps being the same as in the other process.

BLACK PHOTOGRAPHIC COPYING-PROCESS.—TO COPY DRAWINGS IN BLACK LINES ON WHITE GROUND.

(1.)

The following process has been patented by A. Colas, of Neuilly, France. Paper is prepared with the following solution :—½ oz. each of sulphate of iron, sesquichloride of iron, gelatine, and tartaric acid, in 10½ ozs. of distilled water. The paper, kept flat, is stored in a dark closet. When exposed to the light beneath a transparent drawing, the parts influenced by the light lose their greenish-yellow colour. It is afterwards dipped into a bath made of 7 ozs. of gallic acid, ¾ fluid oz. of alcohol, and 1 quart of water. The greenish-yellow lines turn black at once, and the sheet requires only to be rinsed in water.

(2.)

The following is known as the 'Polygraphic' method :—A solution of ½ oz. of aniline colour and 8 drops of glacial acetic acid in 3½ fluid ozs. of water is used as an ink in this process. Japanese paper, a copying press, and a smooth, polished zinc plate are used for producing copies. The paper, after the corners have been moistened, is spread out upon the zinc plate. On the top of the paper is placed a linen cloth, first soaked in water and then wrung out, and on the top of this a sheet of waterproof paper. A cushion formed of ordinary paper by folding it several times together is pressed upon the zinc plate thus prepared. The side of the sheet written on is placed upon the sheet fastened on the zinc plate, and on the top of this a sheet of paper of the same size. The sheets of paper which are to receive the copy must be damped. It is now pressed : in a few minutes the impression will be ready, which can be used at once for 20 to 25 copies. After the impression is drawn off the Japanese paper is removed and the zinc plate washed and cleansed. If 2 pages of a sheet have to be copied, the pages must be enveloped in sheets of paper, which will prevent the ink from one page depositing itself on the other.

The Ferrocyanide Process.

This processs, by which it is possible to make direct positive prints, was the first step taken towards important improvements in the reproduction of drawings. The ferrocyanide paper is prepared with a sensitising solution, the nature of which varies according to the class of work to be done. The following are two formulas :

	Grammes.		Grammes
1. Perchloride of iron	80	2. Tartaric acid	90
Gum	120	Persulphate of iron	110
Citric acid	30	Perchloride of iron	120
Water.	1,000	Gum solution	1,000

This paper when prepared is of a yellow colour ; when exposed to light beneath the tracing important changes take place in the sensitised surface which is not protected by the lines of the drawing. The salts of iron are reduced, the exposed surface becomes white, and as soon as the drawing appears in yellow lines, which can be ascertained by raising the back of the frame, the paper is removed and put in a ferrocyanide or potassium bath, which immediately forms Prussian blue by combining with the iron salts that are not reduced—that is to say, in those parts of the sheet that have been protected from the light. In this way the drawing is developed in a bright blue tint. The sheet is afterwards washed, and then placed in a bleaching bath made up in the proportion of 40 grammes of sulphuric acid and 1,000 grammes of water; finally, the sheet is subjected to a liberal washing, and any spots which do not appear to have been completely bleached are treated with a soft brush.

PHOTO-COPYING.

The simplest outfit for photo-copying consists of a flat frame, a developing bath and rubber squeegee, cutting and trimming table and knife, drying racks, and some metal tubes to hold the sensitised papers. The frame (of ash or oak) has a plate-glass front, a thick sheet of felt, back boards saw cut and battened, pressure bars and springs. In each frame there should be an equal number of boards and bars, and all bars and boards should be interchangeable.

The developing bath consists of an oblong shallow tray ; the larger sizes are fitted with outfall socket and plug. These baths are usually stocked (in zinc) up to 56 ins. by 36 ins. ; for larger sizes, wooden baths lead-lined, or simply made water-tight and provided with a glass or slate slab at the bottom, are generally used. The bath should be fixed with a fall of about ½ in. per ft., so that the water used in developing will flow off readily.

The cutting table is simply a board fitted with a strip of zinc about 6 ins. wide on the upper side, running the full length, and close to the edge. A piece of felt should be tacked to the opposite edge of the table sufficiently large to cover the whole table. This can be drawn over undeveloped prints or sensitised papers. Such a board may be very conveniently supported on trestles. It is often the practice to substitute for the trestles a cabinet of drawers, in which tracings and finished prints can be stored.

The metal tubes for holding the papers should be of tin or zinc, with sliding lids and at least twice the diameter of the roll of paper before unwrapping, otherwise, when unwrapped, it will

expand and be difficult to remove. The simplest form of rack for natural drying consists of two brackets attached to a wall, about 3 ft. 6 ins. apart; clips are attached to the prints when in the bath, a rod is slipped through and the whole hung on the brackets.

A flat squeegee is frequently used for removing the superfluous moisture from the prints whilst lying in the bath. It consists of a thin strip of rubber about 10 ins. long secured in a wooden handle.

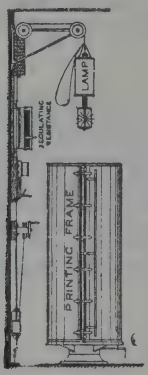

FIG. 1.

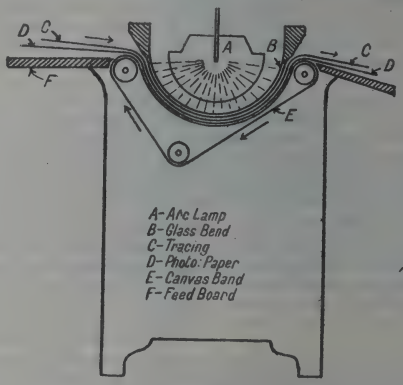

FIG. 2.

The outfit above described is suitable for offices having good daylight and no great pressure of copying work. For large and rapid outputs an electrical outfit is necessary.

Such a machine, capable of taking two tracings, is shown in fig. 1. It is made in several sizes varying from 40 ins. by 27 ins. to 60 ins. by 40 ins. The tracings are clamped closely around a glass cylinder, inside which an arc lamp is alternately raised and lowered until the prints have been fully exposed.

An improved type of copier for a considerably larger output is shown in fig. 3. It enables prints from tracings of any length up to that of a complete roll of paper (30 or 32 feet) to be produced in one piece. The paper A, fed with tracings B, travels slowly downwards between the

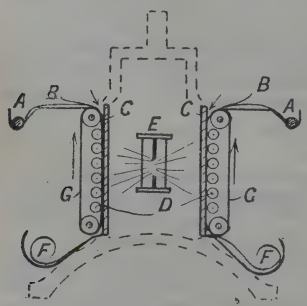

FIG. 3.

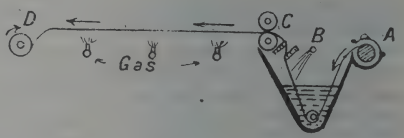

FIG. 4.

glass plate C and an endless blanket G pressed against it by the geared rollers D, passing several fixed arc lamps or one travelling one, E, after which it emerges and rolls up at F ready for trimming and washing.

Continuous printing machines, which are in two sizes, for paper either 30 or 40 ins. wide, are made single or double, the latter printing simultaneously two rolls of paper as in fig. 3. The speed can be varied from 4 feet per minute to 6 minutes per foot on either side so that fast and slow work can be done simultaneously. Fig. 4 shows a 'washing machine.' The roll of prints

is placed in the trough A, passed through a running water-bath and spray B, between squeegees and rollers C, over a series of gas burners, and rolled up dry at D.

Trimming in quantities is usually effected with a guillotine for large work and a trimmer of the Merrett type for smaller sizes.

The 'Hall-Mark' Photo-Copyer.

The 'Hall-Mark,' the latest photo-copying machine, fig. 2, has a Hall-Thorkelin horizontal arc lamp specially designed to throw a richly actinic light downwards without causing a shadow. It is claimed for this lamp that it yields a higher percentage of actinic light per unit of current consumed than any arc lamp hitherto made, and also possesses the unique advantage that the carbons can be adjusted immediately after switching off and without waiting for the lamp to cool.

Beneath the lamp A, which travels automatically from side to side of the machine and across the width of the paper, is a curved glass plate, B, against the underside of which the tracing C, and sensitised paper D, are pressed and caused to travel by an endless canvas belt, E.

The close proximity of the arc light to the glass bend reduces the loss of light to a minimum and enables the machine to be operated at a very high rate of speed. Suitable mechanism provides for a range of from 4 ins. up to 8 ft. per minute.

The frame of the machine is of aluminium and wood for lightness, and everything, including the motor, is self-contained.

A machine taking continuous rolls of 42-in. (wide) paper occupies, including all projections, a floor space of about 5 ft. 6 ins. by 3 ft. 9 ins.

Tracing.

Place the sheet of paper over the drawing to be copied, and lightly rub it over with a ball of wool saturated with benzine; this renders the paper transparent temporarily, when the tracing can readily be made. The benzine by evaporation leaves the paper opaque as before. The benzine must be absolutely pure to secure good results.

MISCELLANEOUS.

To Prevent Rusting-in of Screws.

In machines exposed to heat or moist air the screws soon rust in, even with the use of oil which later on renders it difficult to take the machines apart. By dipping the screws before use in a thin paste of graphite and oil they can be readily taken out, even after years.

Drilling Glass.

To drill holes in glass a common steel drill, well made and well tempered, is the best tool. Moisten with turpentine in which some camphor has been dissolved. Dilute sulphuric acid is also equally good.

To drill a large hole in thin glass, make in a piece of wood a hole of the size required, and fasten the wood with beeswax upon the glass so as to act as a guide. A piece of brass or copper tubing, of the size of the hole required, is placed in the hole in the wood and supplied with emery powder and water, and is twirled round between the fingers or by means of a bow-string. This will cut a hole in a few minutes.

To Divide Glass Bottles.

Breaking glass tubes or vessels with a clean edge by the aid of a string dipped in an inflammable oil is a well-known method, but the latter is not suitable for large vessels, such as a carboy; to break such vessels, fill to point required with cold water, then pour boiling oil over surface of water: before oil has time to cool, dash cold water on outside of vessel, when a clean break is said to result. (*Engineer.*)

To Cut Glass Tubing of Large Diameter.

Nick the glass tube with a file or a cutter at the point where the fracture is desired. Wrap three or four thicknesses of blotting paper around the tube about ½ in. from each side of the mark, the blotting paper being held in place by copper wires. Soak the blotters with water, and expose the narrow section of tube between the two wet blotters to the heat of a bunsen burner. The flame will cause a fracture starting at the file nick and extending in almost a straight line around the tube. (*Power.*)

Cutting Glass under Water.

Cutting a glass dial with a pair of scissors may seem difficult, but it is not, although the job must be done under water and both the glass and scissors must be submerged. A good way is to first cut a paper the size or shape of the glass desired; place it on the under side of the glass for a pattern. It is not expected that it is possible to cut through the centre of a large piece of glass, but by trimming a little at a time a good job can be done. The cutting sensation is a good deal the same as that of cutting cardboard. (*A. Dube, 'Power.'*)

To make Ivory and Bone Permanently White.

Hydrated oxide of zinc is dissolved in ammonia and the articles laid in it. To remove the yellow tint, a few drops of an aqueous solution of blue vitriol is added, until the latter, on being shaken up, turns blue; after impregnation the articles are repeatedly washed with cold water, dried in the air and polished.

Zinc-oxide of ammonia solution is prepared as follows:—40 parts by weight water mixed with 25 parts of pure zinc, with (after a quarter of an hour) 50 parts concentrated hydrochloric acid added.

To the zinc solution 150 parts hot water is added, then (gradually stirring the while) caustic ammonia, until the precipitated white hydrated oxide of zinc is dissolved.

(Scientific American.)

Hard Rubber.

The finest grade of hard rubber, such as is found in a good comb or fountain pen, may contain 75 per cent. rubber and 25 per cent. sulphur, and may have been vulcanised ten hours. The specific gravity of pure hard rubber ranges from 1·12 to 1·25. The tensile strength in the finest and purest grades may be over three tons, and the dielectric strength is specified by the United States Navy for sheets at 10,000 volts per $\frac{1}{32}$ in. of thickness.

Fibre.

There are three kinds of fibre in general use—viz., two kinds of vulcanised fibre, known as hard and flexible, and horn fibre.

The flexible is restricted to such uses as pump valves, washers and gaskets. The tensile strength of vulcanised fibre varies from 10,000 lbs. to 20,000 lbs. per sq. in. (as compared with 3,000 lbs. to 6,000 lbs. for leather). Its resistance to compression varies from 40,000 lbs. to 60,000 lbs. per sq in. (for wood it varies from 3,000 lbs. to 11,000 lbs.). Its resistance to shearing varies from 9,000 lbs. to 13,000 lbs. per sq. in. (compared to wood, with the grain, 225 lbs. to 906 lbs.; to aluminium casting, 12,000 lbs.; and to aluminium forgings, 16,000 lbs.). There is no clearly defined elastic limit, but it approximates 4,000 lbs., and there is no permanent set even at rupture point. The specific gravity is about 1·3, varying from 1·2 to 1·5 (sp. gr. of pure aluminium in a cast state is 2·58; of cork, 0·24; of wood, 0·35 to 1·33). It possesses the strength and density of a metal, yet is elastic and nearly as light as hardwood. A square foot of $\frac{1}{8}$ in. fibre weighs about $\frac{7}{8}$ lb., and the same area of 1 in. stock about 7 lbs.—i.e., about 20 cub. ins. to the pound.

Vulcanised fibre is insoluble in all the ordinary solvents, and is not affected by immersion in alcohol, ammonia, benzine, or any of the animal, vegetable, or mineral oils. It absorbs water freely, and swells when wet, but is not otherwise injured.

When heated, fibre does not melt or soften, but at a high temperature it chars and loses its elasticity. Vulcanised fibre is not brittle, and will stand a great amount of pounding and rough usage. It can be machined, and will take a fine polish, but cannot be moulded.

One of the purposes to which vulcanised fibre is being applied is the thrust bearings in light, sensitive, drilling machines. Ball bearings cause endless trouble in this position if one of the balls fractures or chips, and it has been found that a fibre disc answers the purpose admirably. The permeability of the fibre to oil renders it self-lubricating, and its life under these conditions is remarkable.

To Face Oilstones.

Take a piece of iron with even or straight face (it ought to be planed), scatter a little emery or fine sand on the iron plate, add a little water, and rub the face of the stone, renewing the emery or sand and water as requisite, finishing with an addition of water without emery or sand.

Ink for Writing on Metal.

Chloride of platinum, $\frac{1}{2}$ oz.; soft water, 1 pint. Use with a quill pen.

Etching and Etching Fluids.

The nearest approach to a perfect ground for general purposes is beeswax of the proper consistency, which can be easily applied in any desired thickness. Before applying the wax it is important that the surface be thoroughly clean and absolutely dry, and the difference in temperature between the wax and the article to be etched should be slight. If it is necessary to dip the piece into melted wax, the article should be kept immersed for a few moments until it acquires the same temperature as the molten wax.

The following fluids have been tried on various substances and found to work satisfactorily:

Iron and Steel.—Hydrochloric acid (full strength) should be used. Nitric acid, however, must not be used.

Brass.—Nitric acid.

Copper.—A mixture containing 2 parts of nitric acid and 1 part sulphuric acid.

Silver.—Nitric acid, 3 parts; water, 1 part.

Gold.—A mixture containing 1 part of nitric acid and 3 parts of hydrochloric acid. This mixture should be prepared just before being applied, and should be used warm, under a hood or fume closet.

Platinum.—The same mixture as that used for gold.

Lead.—Nitric acid.

Aluminium.—A 10 per cent. solution of caustic soda or potash.

Zinc.—A mixture containing equal parts of hydrochloric acid and water, used warm.

Glass.—Hydrofluoric acid. The article may be immersed in the liquid acid for a few minutes or it may be exposed to the fumes for five to fifteen minutes. Extreme caution should be used in handling this acid, using rubber gloves for the hands and a lead or hard rubber container for the acid. Contact with the skin will cause severe burns, and the action seems to be continuous, producing burns far more severe than those caused by the mineral acids.

All of the acids may be used full strength and will act instantly, but if the etching is to be of considerable depth most of them may be diluted with water before applying. This will require more time, but will produce a cleaner cut. The exception to this is the mixture of gold and platinum, which must always be used full strength and applied as warm as the melting point of the wax will permit. (*A. Schleimer, 'Machinery'.*)

To Bend Zinc Tubes.

Put a cork into one end and fill with slightly damp sand well rammed in, then close with another cork; heat the tube until it is just uncomfortably hot to the hand, and then bend round a bit of board sawn to the required curve.

To Drill Hard Steel.

Use turpentine instead of oil; it will drill readily when the drill will not touch the metal with oil.

Aluminium Working.

One of the best lubricants for cutting aluminium in the lathe is kerosene oil; this prevents tearing, and enables a better finish to be obtained.

To Remove a Stubborn Nut.

Heat the spanner end and place on nut for a moment or two; this will expand the nut only, whereas using a blow-lamp, etc., heats both nut and bolt. If the above method fails the nut should be split.

Steel-Facing Electrotypes.

A film of pure iron of such hardness as to resemble steel (hence the process is named 'steel-facing') may be deposited on the face of an electrotype. The solution for the purpose is made as follows:—Dissolve ½ lb. of iron sulphate (green vitriol) in half a gallon of rain-water, and add a solution of ammonium carbonate until all the iron has been precipitated. Wash the precipitate by pouring on water and allowing to settle, finally draining off all water possible. Then dissolve the wet precipitate in just sufficient sulphuric acid to avoid having any free acid, and use this as the depositing solution in as concentrated a form as possible. As the solution has a tendency to become acid by working it, this must be corrected by using an anode plate of pure iron eight times larger than the electrotype to be faced, and placing a plate of platinum in the solution, attached to the iron anode, when the solution is not at work.

Another solution, suitable to larger operations, is made as follows:—Dissolve 56 lbs. of ammonium carbonate in 35 gallons of water. In this place a large anode of charcoal iron, and a small cathode of the same connected with a battery, and dissolve into the solution until a test strip of copper is nicely coated with iron in a few minutes. Work this, and all other iron solutions, with a weak current—a battery of Daniell cells will do—keep the anode clean, and add free ammonium carbonate as required. The voltage necessary to work any solution and give best results must be found by experience, always bearing in mind that iron solutions yield their metal in best condition at a low voltage. Iron solutions are also liable to change from atmospheric influences, the iron in solution becoming oxide by contact with light and air. To minimise this trouble, keep the solutions covered. If a moderately thick coat of iron is desired, the electrotype must be taken out every four or five minutes, and the face scrubbed in clean water, then replaced in the bath. When the coat is thick enough it should be well washed in hot water and rapidly dried, then oiled, and then brushed over with benzine. If not used at once it must be protected from rust by coating with a film of wax.

Silvering a Mirror.

(14 square inches area.)

Well scrub glass with brush, soap, and hot water; rinse repeatedly in cold water; soak in nitric acid for few minutes; rinse in distilled water. Do not touch surface after soap stage.

Solutions.

(*a*)	
Silver nitrate	50 grs.
Distilled water	1 oz.
(*b*)	
Grape sugar	50 grs.
Distilled water	1 oz.
(*c*)	
Caustic potash	50 grs.
Distilled water	1 oz.

Add strong ammonia drop by drop to (*a*), when a yellowish precipitate will form, and later liquid will clear. No more ammonia must then be added; swirl after each drop. Add (*c*), when black precipitate will form; add ammonia drop by drop until solution clears; add 2½ ozs. distilled water and mix in sugar solution (*b*). *Immediately* put into dish and carefully insert glass with face (downwards) just below the surface. When sugar is added solution becomes cloudy, so it should only be added when quite ready for use. Leave glass undisturbed for 30 minutes. Remove glass and again wash in distilled water. Drain for few minutes and swish off any drops of water. If cloudy, polish with a pad of cotton wool covered with soft chamois leather and jewellers' rouge, by light circular strokes. Lacquer with No. 2 cold colourless lacquer from Messrs. Gedge, 90 St. John's Street, Clerkenwell. Back with Brunswick black.

Size of Clock Dials.

Allow 1 ft. diameter for every 10 ft. from the ground, and then add 6 ins. to this; thus, if the dial is to be 40 ft. from the ground, the diameter should be 4 ft. 6 ins.

Flow of Sand.

The velocity of flow of sand and other fine materials through openings of various shapes and in different circumstances is determined mainly by the size of the particles and of the opening, but is slightly diminished by angularity of the particles or by moisture on them. The specific gravity of the particles, the height of the material above the opening, and the shape of the upper contour of the material have little effect. If D is the diameter of the opening, and *d* that of the particles, both in inches, the mean velocity of flow V in feet per second is given with sufficient accuracy for most practical purposes by the equation. $V = (D - 2\,d)/\sqrt{D}$.

(*Hersam: Journal of the Franklin Institute.*)

Wire Drawing.

With Diamond Dies.—The diamonds used are partly natural stones and partly chips from large stones used in jewellery; some of them also are stones which have proved too hard for the jeweller to polish. For a hole ·055 in. in diameter a 5-carat stone is needed, whilst stones weighing half-a-carat suffice for dies with holes from ·014 in. down to ·009 in. in diameter and under. In copper wire the smallest size made commercially is 0·002 in. in diameter. Thirteen diamonds are needed to reduce the wire from ·010 in. in diameter to 0·003 in. in diameter. Wires thinner than ·002 in. in diameter are exceedingly expensive to make. A lot drawn for exhibition purposes from ·0022 in. in diameter down to ·001 in. in diameter took 7 drafts. The life of the diamonds when drawing copper wire is six months to a year, provided the stones are of good size, hard, smooth, and well drilled. The weight produced per operator per day falls very rapidly as the size of the wire is reduced. Thus, whilst one man will produce 1,100 lbs. per day of No. 22 (B. and S. gauge), he can only draw 45 lbs. of No. 40 (B. and S.). Diamonds are also used for drawing steel, though they are not economical, nor do they produce a better quality of wire than steel die-plates; but if fine steel wire is wanted very round and true to size, the diamond dies seem necessary. A steel die will not keep to size for more than one coil of No. 33 wire or finer. The life of a diamond is much shorter on steel than on copper, averaging only about three days, when it must be polished out for the next larger size. The surface produced on steel wire is not so smooth when diamonds are used as it is with steel. The speed at which the wire is drawn appears to have little effect on the life of the diamond die, which depends solely on the length passed through. About 200 lbs. weight of steel wire can be drawn through a No. 32 (B. and S.) diamond die-plate before it is off size, 15 lbs. through holes ·005 in. to ·003 in. in diameter, and less than 1 lb. through holes smaller than ·002 in. in diameter. The smallest commercial size is ·0025 in. steel brush wire, drawn from low or medium carbon steel. Difficulty was at one time experienced in drawing hard music wire smaller than ·012 in. in diameter without breaking the diamond; but nowadays it can be drawn as small as ·005 in. in diameter, using 2 to 2½-caras diamonds for the dies. Below about ·009 in. or ·008 in. diameter, however, music wire becomes very curly, and no method of keeping it straight has yet been discovered. (*S. Barnett.*)

Cracks in Metal

A crack in a piece of metal is prevented from extending further by the well-known means of drilling a hole where the rent ends; but when the hole is not bored on just that spot the crack is apt to continue beyond the hole. To facilitate the search for the exact point, moisten the cracked surface with petroleum, then wipe it, and immediately rub it with chalk. The oil that has penetrated into the crack exudes, and thus indicates with precision where the crack stops.

Rendering Celluloid Incombustible.

In order to overcome the undesirable quality of celluloid to ignite, a French chemist has adopted the following method: An ether-alcohol solution of celluloid is made; then an ether-alcohol solution of ferric perchloride. The two solutions are mixed, and a clear syrupy liquid is obtained, of yellow colour, yielding no precipitates. The liquid is poured into a suitable vessel and is left for spontaneous evaporation, and a substance of shell-colour is produced, which, after washing and drying, gives the desired result. The celluloid thus treated loses none of its properties of pliability and transparency, and is not only uninflammable, but it is also incombustible.

Another method by which the celluloid may be rendered uninflammable, based on the same principle, consists in mixing bromide of camphor with cotton powder, adding castor-oil to soften the substance so that it may be less brittle. This product, though more easily prepared, is, however, not incombustible like the former preparation.

Wood-worms in Westminster Hall Roof.

The extermination of the *Xestobium tessellatum* in the oak roofing of Westminster Hall has been effected by spraying the timber with a mixture of 50 per cent. tetrachlorethane, 6 per cent. cedarwood oil, 2 per cent. solvent soap, 2 per cent. paraffin wax, and 40 per cent. trichlorethylene. The tetrachlorethane is a perfect insecticide, but it is so dangerous that those who handle it must use gas masks.

It is stated that the most effective means of treating oak work when attacked with wood-worm is to give it several coats of paraffin, well soaked into the wood. This should be done by a careful workman, making quite sure that every hole has been well soaked with the paraffin; if treated with paraffin it does not damage the oak, but has a tendency to improve the colour.

Thermostatic Metal.

Thermostatic metal, manufactured by the *British Thomson-Houston Company, Ltd.*, in appearance a homogeneous metal, is formed of two metal strips having widely different coefficients of expansion. The two metals are welded together along their entire length, and are quite inseparable under normal working conditions. When the duplex strip is subjected to change of temperature, one half will expand more quickly than the other, causing the strip to bend. A single degree of temperature change is said to affect its curvature to a measurable extent, and practically instantaneously. In bending, it exerts a force sufficient for the direct operation of levers, the opening and closing of ventilators, etc. The metal can be cut, stamped, or machined. It is supplied in various thicknesses from 0·015 in. to 0·25 in.

Setting a Spirit-Level Glass.

A simple method of setting a spirit level glass is to use a small piece of putty to support each end temporarily. The plastic putty can be made to hold the glass in the required position, it being an easy matter to depress either end so that it will be parallel or level with the working surface of the levelling bar. When properly levelled up in this way plaster of Paris is poured around the supporting ends of the glass and allowed to set. The glass will then be held permanently in place. (J. H. B., *Machinery*).

Supporting Power of Ice.

THE METRIC SYSTEM IN CONNECTION WITH INTERNATIONAL TRADE. (pages 2673-2675)

(Contributed by A. H Allen, M.I.E.E.)

SECTION XLI

PART I

LENGTHS—SURFACES—WEIGHTS—CAPACITIES—FOREIGN MEASURES—WIRE-GAUGES—SIZES OF PAPER, etc.

(Revised by S. W. Attwell, of the National Physical Laboratory.)

The accepted relations of English Imperial to International Metric Measures are thus given by the Standards Office of the Board of Trade :

1 inch = 25·399978 mm. ; 1 metre = 39·370113 inches ; 1 gallon = 4·5459631 litres ; 1 litre = 1·75980 pint ; 1 pound = 0·45359243 kilogram ; 1 kilogram = 2·2046223 pounds.

In 1893 the United States of America recognised the metre as the fundamental standard of length, and adopted the conversion value of 1 metre = 39·37 inches.

10 penny diameters = 1 ft. ; halfpenny = 1 inch ; 5-shilling piece = 1½ inch. Weight of 3 pennies, 1 five-shilling piece, or 5 shillings, each = 1 oz.

LENGTHS.

English.

The length of the standard yard of 36 inches is such that a pendulum vibrating seconds of mean time, temperature 62° F., at the level of the sea and latitude of Greenwich, has a length of 39·1393 inches.

Miles.	Furlongs.	Chains.	Rods.	Yards.	Feet.	Inches.

GUNTER'S SURVEYING CHAIN.

7·92 inches = 1 link. 100 links = 1 chain 4 rods, or 22 yards. 80 chains = 1 mile.

ROPES AND CABLES.

1 cable-length = 120 fathoms = 720 feet. 1 fathom = 6 feet.

GEOGRAPHICAL AND NAUTICAL MEASURES.

1 degree of a great circle of the earth round the equator = 69·174 statute miles = 365,239 feet. 1 nautical mile (knot) = 6,080 feet. 1 telegraph mile = 6,087 feet.

LOG-LINE.

The log-line should be about 150 fathoms long, and 10 fathoms from the log to the first knot on the line. If half-a-minute glass is used, it will be 51 feet between each succeeding knot. For 28-seconds glass it will be 47·6 feet = 7·93 fathoms per knot. This is the length of knot by calculation, but practically it is shortened to 7·5 fathoms per knot for 28-seconds glass.

WEIGHTS.

English.

One cubic inch of distilled water (weighed in air against brass weights) at temperature 62° F., the barometer being at 30 ins., weighs 252·326 grains, of which 7,000 go to the pound avoirdupois, and 5,760 to the pound troy.

The Metric Carat.

By decision of the Standards Department of the Board of Trade, the metric carat of 200 milligrams, and its necessary multiples and sub-multiples, are standard weights in the United Kingdom.

CAPACITIES.

English.

Gallon.—The standard gallon (*International Bureau of Standards, Paris*, 1921) measures 277·420 cubic inches, and contains 10 lbs. (avoir.) weight of distilled water (weighed in air against brass weights) at the temperature of 62° F., the barometer being at 30 ins.

APOTHECARIES' MEASURES.

Gallon (C) = 8 pints (O) ; 1 pint = 20 fluid ounces (oz. weight of water).
Ounce (f℥) = 8 drachms (f℈) = 480 minims (♏) = 720 drops (gtt).
One wine-glass = 4 tablespoonfuls = 16 teaspoonfuls = 2 ounces.
Symbols.—f. or fl., fluid ; ss., one half ; aa., for each. Thus, f℥ss. means $\frac{1}{2}$ a fluid ounce.

Conversion of Metrical to English Capacities.

Cub. Centimetres to Cub. Ins.	Litres to Fluid Ounces.	Litres to Pints.	Litres to Gallons.

Care should be taken to distinguish the difference between Stubs' Iron Wire Gauge and Stubs' Steel Wire Gauge. The former is commonly known as the English Standard Wire or Birmingham Wire Gauge, and designates the Stubs' *Soft* wire sizes.

The Stubs' Steel Wire Gauge is the one employed in measuring drawn steel wire or drill rods of Stubs' make, and is also used by some makers of American drill rods.

(*Brown and Sharpe*)

VARIOUS FOREIGN WEIGHTS AND MEASURES WITH THEIR APPROXIMATE BRITISH EQUIVALENTS.

(Compiled by the Board of Trade (July 1923) from information published by the respective Governments.)

[NOTE.—In the case of fractional equivalents the last figure shown is uncertain.]

Country.	Length.	Area.	Weight.	Capacity.	Approximate British Equivalent.
1. United States of America	—	—	Barrel (flour)	—	196 lbs. avoir.
	—	—	Short Ton	—	2,000 lbs. avoir.
	—	—	Long „	—	2,240 „ „
	—	—	—	Bushel (Winchester)—dry	0·96897 imperial bushel.
	—	—	—	Gallon (Old English)—wet	0·83268 „ gallon.
	Metre	—	—	—	1·09361 yards.
	Kilometre	—	—	—	0·62137 mile.
	—	Sq. Kilometre = 100 Hectares	—	—	0·38610 square mile.
	—	Are	—	—	0·024711 acre.
	—	Hectare	—	—	2·4711 acres.
2. Austria	—	—	Kilogramme	—	2·20462 lbs. avoir.
	—	—	Quintal métrique (Centner) = 100 kilogs	—	220·462 lbs. avoir.
	—	—	Tonne	—	2204·62 lbs. avoir.
	—	—	—	Cubic metre	1·30795 cubic yards.
	—	—	—	Hectolitre (liquid)	21·9975 imperial gallons.
	—	—	—	„ (cereals)	2·74969 „ bushels.

SECTION XLI

PART II

THE METRIC SYSTEM IN CONNECTION WITH INTERNATIONAL TRADE.

(A. H. Allen, M.I.E.E.)

The decimal multiples and submultiples of the metre (the length standard) in general use are the kilometre (1,000 m.), centimetre ($\frac{1}{100}$ m.), and millimetre ($\frac{1}{1000}$ m.); in scientific work the micron ($\frac{1}{1000000}$ m.) is used. In surface measurements the square metre, centimetre, and millimetre are used for industrial purposes, and the are (100 sq. metres), hectare (100 ares or 10,000 sq. metres), and the square kilometre (1,000,000 sq. metres), for land measurement. For the measurement of volume the principal unit is the litre*($\frac{1}{1000}$ cub. metre or 1,000 cub. centimetres); the cubic metre and the cubic centimetre ($\frac{1}{1000000}$ cub. metre) are in common use.

The units of weight are the gramme, the kilogram (1,000 grammes, or the weight of a litre of water at its maximum density), and the metric ton (1,000 kilograms); the quintal (100 kilograms) is also used in commerce, and submultiples of the gramme in laboratory work. The following are the abbreviations employed to denote the units, their metric and English equivalents, and approximate values of the latter:—

Name.	Abbn.	Metric Equivt.	English Equivt.	Approx. Value.
Millimetre . .	mm.	0·001 m.	0·03937 inch	$\frac{1}{25}$ inch
Centimetre . .	cm.	0·01 m.	0·3937 inch	$\frac{2}{5}$ inch
Metre . . .	m.	1·0 m.	1·0936 yard	$1\frac{1}{10}$ yard
Kilometre . .	km.	1,000 m.	0·6214 mile	$\frac{5}{8}$ mile
Square centimetre .	cm².	0·0001 m².	0·155 square inch	$\frac{1}{6\frac{1}{2}}$ square inch
Square millimetre .	mm².	0·000001 m².	0·00155 square in.	$\frac{1}{640}$ square inch
Square metre . .	m².	1·0 m².	1·196 square yard	$1\frac{1}{5}$ square yard
Are	a.	100 m².	0·02471 acre	$\frac{1}{40}$ acre
Hectare . . .	ha.	10,000 m².	2·471 acres	$2\frac{1}{2}$ acres
Square kilometre .	km².	1,000,000 m².	0·3861 square mile	$\frac{3}{8}$ square mile
Cubic centimetre .	cm³.	$\frac{1}{1000000}$ m³.	0·0610 cubic inch	$\frac{1}{16}$ cubic inch
Litre . . .	l.	$\frac{1}{1000}$ m³.	1·7598 pints	$1\frac{3}{4}$ pint
Cubic metre . .	m³.	1·0 m³.	1·308 cubic yard	$1\frac{3}{10}$ cubic yard
Gramme . . .	gm.	$\frac{1}{1000}$ kg.	0·03527 oz.	$\frac{1}{30}$ oz.
Kilogram . .	kg.	1·0 kg.	2·2046 lb.	$2\frac{1}{5}$ lb.
Quintal . . .	ql.	100 kg.	1·9684 cwt.	2 cwt.
Metric ton . .	t.	1,000 kg.	0·9842 ton	1 ton

*Some misapprehension exists with regard to the difficulty of conversion from English to metric measures and *vice versa*. When such operations are necessary, they are readily performed with the aid of printed tables, of which many varieties are available at small cost. But in point of fact, conversion would not be required except on rare occasions if the metric units were in general use. Under the conditions existing in this country, conversions from one English unit to another are constantly called for, as in reducing cwt. to lbs., or feet to miles, involving calculations at least as arduous as the conversion from English to metric measures, but when the use of the metric system is universal similar changes will be made by simply moving the decimal point. Thus, to reduce 25·78 kilometres to metres, all that is required is to write down 25,780 metres, and to find the volume occupied by 47·31 litres one need only write down 47,310 cubic centimetres, or 0·04731 cubic metre. Only during the process of changing from the present units to the metric system would conversion be frequently necessary.

Another common error is to suppose that the convenient binary divisions of a unit, especially the half and quarter, could not, or should not, be used in connection with the metric system; on the contrary, in countries which have adopted the metric system these divisions are in common use, and there is no reason why other vulgar fractions should not be employed, if desired, except that by doing so a great deal of unnecessary labour would be incurred, as in the case of the English units at present, and one of the greatest advantages of the metric system would be needlessly sacrificed. In workshops where the inch subdivided into sixty-fourths is now used, it is necessary in order to employ screw micrometers or verniers, to make use of printed tables for converting these awkward fractions into decimals of an inch, and in order to avoid this grave inconvenience some manufacturing firms dimension their drawings entirely in inches and mils. These difficulties are never experienced where the metric system is in vogue.

Again in finding the weight of a body of irregular shape from the drawings, a common requirement in engineering work, it is necessary to ascertain the volume in, say, cubic inches, and multiply this by the weight of a cubic inch, which must be obtained from tables, and if the tables give the weight per cubic foot but not per cubic inch, as often happens, one or other figure must be converted with the multiplier or divisor 1,728; or if the specific gravity of the material only is obtainable, this has to be multiplied by the weight of a cubic inch of water in order to obtain the weight of a cubic inch of the material. In the metric system, on the other hand, nothing but the specific gravity is ever necessary; this multiplied into the volume in cubic centimetres at once gives the weight of the body in grammes, from which the weight in kilograms or tons is obviously obtained by shifting the decimal point three or six places to the left without any calculation.

In the engineering industries there is much to gain by the adoption of the metric system, in addition to the commercial advantage resulting from the use of the same units as our foreign customers. Drawings would be figured throughout in millimetres, thus avoiding the necessity of marking the denominations of the units, with the resulting liability to error, and the difficulties of adding up a series of dimensions involving eighths, sixteenths, and thirty-seconds correctly would be obviated, whilst much time would be saved. Where calculations were necessary, the trouble and time involved in reducing fractional dimensions to decimals would be avoided, and the liability to error in this operation would be removed. It may be argued that error will arise in placing the decimal point; if this is so, it applies equally to the English measures, for this question only arises when multiplication or division is involved, the position of the point remaining unaltered in addition and subtraction and if an error of this kind were made it would be so large as to be readily discovered by inspection.

During the war, still more than in peace time, it was found necessary in many workshops to use both English and metric measures side by side. No difficulty has been experienced as a result of this, works managers stating that the workmen readily adopt the metric measures, whilst in cases where jigs and gauges are used they need not even know what the dimensions are. In all work for which limit gauges are used, the dimensions are always stated in decimals, whether English or metric. In changing from one system to the other, the gauges need not be altered at all; it is the size of the part, not the name of the size, that is important. This applies also to jigs and templates. In the case of screw threads, which are usually cut with dies and taps, the Whitworth standards can be retained, as the only measurements required relate to the size of the stock, not to the threads. The dimensions of screws smaller than the smallest true Whitworth size ($\frac{1}{4}$ inch) were standardised years ago by a British Association Committee, on the metric system, and need not be changed. Metric screws can, if desired, be cut in a lathe with an English leading screw, if one wheel is added to the change wheels, having 63 or 127 teeth.

An important question is that of the metric unit which takes the place of the mil, or one-thousandth of an inch, which under modern conditions of accuracy of workmanship is very generally employed as the actual working unit of length for fitted parts, although the fact may not be so generally realised. The answer is that the one-hundredth of a millimetre admirably meets the requirements, being practically equal to four-tenths of a mil. For very fine work, dimensions are frequently stated in tenths of a mil, but are usually accompanied with a tolerance or margin or error which reduces the limit of accuracy to like something half a mil. The latter is, in fact, according to the National Physical Laboratory, in a report to the Engineering Standards Committee,* a degree of accuracy of measurement which is seldom attained in the workshop, and of course the accuracy of the work is still lower, except in the tool-room, where entirely special conditions obtain. In the report above referred to, it was shown, as the result of a long investigation, that the average error was over $1\frac{1}{2}$ mils, and individual errors amounted often to two or three mils, even in the case of high-class workmanship on plain cylindrical work. Hence the hundredth of a millimetre provides sufficient margin for all purposes in the workshop, and where extreme accuracy is necessary, as in making gauges and other tool-room operations, the thousandth of a millimetre (less than half a ten-thousandth of an inch) is the utmost that is required. As a matter of fact, a large proportion of workshop dimensions can be stated with sufficient accuracy to the nearest millimetre, and even in the case of machined and fitted parts the great majority of dimensions need not be figured to a finer subdivision than one-tenth of a millimetre. Hence

* Now the British Engineering Standards Association.

there is no necessity for a 'string of decimals,' even when converting inch measurements on a drawing to millimetres; if the metric equivalents are given to the tenth of a millimetre the departure from exactitude cannot be as great as two mils, and if they are given to the hundredth, i.e. to two decimal places, the inaccuracy cannot exceed one-fifth of a mil. On the other hand, in accurate work requiring the use of gauges, with dimensions given to a finer value than $\frac{1}{500}$ inch, decimal figures are freely used in English measures, running to the third and even the fourth place on drawings figured in inches, and lists of standard sizes and tolerances, such as those issued by the British Engineering Standards Association, absolutely bristle with decimals. Such dimensions cannot be stated in 32nds and 64ths. Thus there is no novelty in the use of the decimal system in connection with inch measurements, and those who have to use these drawings are already of necessity familiar with the handling of decimals. As a matter of fact, they are obliged to keep at hand printed tables of decimals equivalent for the binary subdivisions of the inch.

Perhaps the chief objection to the use of the metric system in British workshops is the fact that much of the raw material, such as metal rods and bars, sheets, etc., is obtainable at present only in round figures based on the inch, and the dimensions of this material in some cases control those of the machines and tools (but mainly the tools) by which they will be worked upon. As it is desirable to use round figures wherever possible, especially for stock material, the adoption of the metric system would necessitate eventually slight modifications of all such standard sizes, to make them even millimetres or decimals of a millimetre, and during the transitional stage stocks of both denominations would have to be made and sold. This, however, would be a temporary matter, and could hardly outweigh the advantages of falling into line with the vast bulk of our foreign customers in this respect.

SECTION XLII

PATENTS, TRADE MARKS, AND DESIGNS

(Contributed by a Chartered Patent Agent.)

SECTION XLII

PATENTS, TRADE MARKS, AND DESIGNS.

(Contributed by a Chartered Patent Agent.)

PATENTS.

Application for a patent must be made by the inventor or inventors either alone or in conjunction with one or more co-applicants or a limited company. By inventor is understood either the actual inventor or a person who first introduces an invention from abroad or to whom an invention is communicated from abroad.

When an application is made it is accompanied by either a 'provisional' or a 'complete' specification. In the former case the specification must describe the nature of the invention, but need not particularly describe the same, and the applicant has the right to use and publish the invention during nine months from the date of application, which time may be employed in perfecting the invention and in applying for foreign patents. This protection against the consequences of use and publication is known as Provisional Protection. Should a complete specification not to be filed within the prescribed period of nine months, the application is deemed to be abandoned, and no official publication of the provisional specification takes place. When the application is accompanied by a complete specification, full protection is obtained from the date of the acceptance, and between this date and that of the sealing of the patent the applicant has all the privileges and rights accorded by the patent, except that he will not be entitled to institute any proceeding for infringement, unless and until a patent for the invention has been granted.

When a provisional specification has been filed and it is not desired to abandon the application, a complete specification must be filed within nine months from the date of filing the provisional specification; one month's extension of this time, however, can be obtained on payment of a fee. In such a case the complete specification must describe substantially the same invention as that the nature of which is disclosed in the provisional specification; if not, the Comptroller may require the complete specification to be amended to avoid any disconformity between the two specifications.

A complete specification—whether filed with the application or after a provisional specification—must fully describe (if necessary with the assistance of drawings) the manner of carrying out the invention in practice, and at the same time clearly and correctly point out the features of novelty by a distinct statement of the invention claimed. The complete specification on being filed is submitted to an examiner who makes an investigation to ascertain whether the invention described therein has been wholly or in part claimed or described in any specification (other than a provisional specification not followed by a complete specification) published before the date of the application, and deposited pursuant to any application for a patent made in the United Kingdom within fifty years next before the date of the application, or in the complete specification of any prior application, although such complete specification may not have been filed when the application was made. If any anticipating specifications are found, the applicant will have the opportunity of amending the specification, and, if the amendment is not effected to the satisfaction of the Comptroller, the Comptroller may insert a reference to any of the prior specifications in the specification by way of notice to the public. Where the Comptroller is satisfied that the invention has been wholly and specifically claimed, he may refuse to grant a patent.

When an applicant has two or more provisional applications running concurrently and the subject-matter of such applications is of such a nature as to constitute a single invention which may properly be covered by one patent, the Comptroller may accept one complete specification in respect of the whole of such applications and grant a single patent thereon bearing the date of the earliest of such applications; in case of legal proceedings, however, the respective dates of the several applications may be considered.

Patents of addition for improvements in, or modifications of, an invention already patented may be applied for for any unexpired term of the original patent, and no renewal fees, other than those payable in respect of such original patent, will be payable.

Great Britain is a party to the International Convention for the protection of industrial property, under which an applicant for a patent in any one of the States being parties to the Convention may obtain priority in any of the other States—that is to say, an application may be made in any such States, notwithstanding that publication of the invention may have been made therein, providing that such application be filed within twelve months from the date of the original application.

When a complete specification has been accepted such acceptance is advertised, and the specification will be open to public inspection. Notice of opposition to the grant of a patent may be given at any time within two months from the date of such advertisement, but on the following grounds only, viz. :—

(*a*) That the invention was obtained from the opponent or from a person of whom he is the legal representative.

(*b*) That the invention has been published in the complete specification of a British patent filed in the United Kingdom within fifty years before the date of application for the patent, the grant of which is being opposed, or has been made available to the public by publication in any document (other than a British specification) published in the United Kingdom prior to the application.

(*bb*) That the invention has been claimed in the complete specification of a British patent which, though not published at the date of the application for a patent, the grant of which is opposed, was deposited pursuant to an application for a patent which is, or will be, of prior date to such patent.

(*c*) That the nature of the invention or the manner in which it is to be performed is not sufficiently or fairly described in the complete specification.

(*d*) That the complete specification includes matter not in the provisional specification, and forms the subject of an application made by the opponent in the interval between the leaving of the provisional and complete specifications.

(*e*) That, in case of an application under the International Convention, the specification describes or claims an invention other than that for which protection has been applied for in a foreign state or British possession, and that such other invention forms the subject of an application made by the opponent in the interval between the leaving of the application in the foreign state or British possession and the leaving of the application in the United Kingdom.

If there is no opposition, or, in case of opposition, if the determination is in favour of the grant of a patent, the Comptroller causes a patent to be sealed.

The decision of the Comptroller in most cases is subject to appeal to the Law Officer.

Letters patent extend to Great Britain, Ireland, and the Isle of Man, and are granted for sixteen years, subject to the payment of renewal fees commencing at 5*l.* in respect of the fifth year, and increasing 1*l.* for each succeeding year during the term of the patent, the last payment being 16*l.* These renewal fees are payable before the commencement of the year in respect of which the payment is made, but extensions of time for making these payments up to three months can be obtained, with the addition of a fine, and in the event of a patent lapsing through the non-payment of a fee, the Comptroller is empowered to revive the patent on certain conditions.

At any time after the sealing of a patent the Comptroller may, if requested by the patentee, cause the patent to be endorsed with the words 'licences of right' and any person shall then be entitled, as of right, to a licence under the patent upon such terms as, in default of agreement, may be settled by the Comptroller.

Furthermore, any person interested may apply to the Comptroller alleging that there has been an abuse of the monopoly rights under a patent and asking for relief. Such rights will be deemed to have been abused, if, after four years from the date of the patent, the invention—being capable of being worked in the United Kingdom—is not being worked on a commercial scale; or if such working is being prevented or hindered by the importation from abroad of the patented article; or if the demand for the patented article is not being met to an adequate extent and on reasonable terms; or if trade or industry is being prejudiced by refusal to grant licences, or by conditions attached by the patentee to the purchase, or use of the patented article or to the working of the patented process. If the Comptroller is satisfied that an abuse of the monopoly rights has been proved, he may order the patent to be indorsed with the words 'licences of right' and grant a licence to the applicant on such terms as he may think expedient; or he may order the patent to be revoked.

For 'PATENT SPECIFICATION DRAWINGS,' see page 190.

TRADE MARKS.

Trade marks are registered under the Trade Marks Act of 1905 as amended by the Act of 1919, which provides that a registrable Trade Mark must contain, or consist of, at least one of the following essential particulars :—

1. The name of a company, individual, or firm represented in a special or particular manner.

2. The signature of the applicant for registration or some predecessor in his business.

3. An invented word or invented words.

4. A word or words having no direct reference to the character or quality of the goods, and not being, according to its ordinary signification, a geographical name or a surname.

5. Any other distinctive mark; but a name, signature or word or words, other than such as fall within the descriptions in the above paragraphs 1, 2, 3, and 4, shall not be registrable under the provisions of this paragraph except upon evidence of its distinctiveness.

Provision is also made for the registration of any special or distinctive word or words, letter, numeral, or combination of letters or numerals used as a Trade Mark by the applicant or his predecessors in business before the 13th August, 1875, and which has continued to be used down to the date of the application for registration.

The Trade Marks Act of 1905 as amended by the Act of 1919 provides for a new kind of registration of Trade Marks whereby certain marks, not registrable under the principal Act, can now be registered, provided they have been in *bona-fide* use in the United Kingdom for not less than two years. For this purpose the Register is divided into two parts called Part A and Part B, the new kind of marks being registered in Part B.

An application for registration is made on a form bearing the necessary stamp and should be accompanied by four additional representations of the mark properly mounted. The application is then examined and the mark compared with other marks on record in the Trade Marks Office (this provision may be dispensed with in the case of application to register in Part B), and if, in the opinion of the registrar, any mark or marks be found having such resemblance to the mark sought to be registered as to be calculated to deceive, the applicant will be notified of the conflicting mark or marks, and if, within one month from the date of issuing such notice, no action is taken by the applicant the application will be deemed to be abandoned. Should, however, the applicant so desire, the registrar will appoint a hearing in order that the applicant may attend before him, when the registrar will decide whether the application can proceed. Appeal can be taken from the decision of the registrar to the Board of Trade.

When an application is allowed the mark is advertised in the Official Journal of the Trade Marks Office. The application is then open to opposition for one month from the date of the Journal in which the advertisement appears, and should no opposition be entered the registrar will, upon payment of the registration fee, issue his certificate of registration.

The term of registration of a Trade Mark is fourteen years and may be renewed.

DESIGNS.

For articles which do not form the subject of a patent, protection may in some cases be obtained by design registration where the novelty consists of shape, pattern or ornamentation. Copyright is granted for five years and is renewable for a further similar term, and it is within the discretion of the Comptroller of Patents and Designs to extend the term of a copyright for a third period of five years.

SECTION XLIII

COST OF ENGINEERING WORKS

(Contributed by John T. Rea, Author of 'How to Estimate')

SECTION XLIII

COST OF ENGINEERING WORKS.*

(Contributed by John T. Rea, Author of 'How to Estimate.')

AERIAL ROPEWAYS.

Two broad types—Single-rope or Monocable, and Double-rope or Bi-cable. In the former the load carriers hang from and move with an endless hauling wire rope, for gradients up to 1 in 4; in the latter the load carriers hang from a fixed wire rope (double line), and are drawn along with an endless hauling rope, for any gradient.

Aerial ropeways fixed complete, including wire ropes, pulleys, carriers, wooden supports, engine, driving gear, machinery, labour, etc., to carry 10 or 20 tons per hour, in loads not exceeding 5 cwts. per carrier, and gradients as above, pre-war costs :—

	Per Mile. £	£
Running single-rope system, to carry 10 tons per hour	900	to 1,200
" " " 20 "	1,400	" 1,700
Fixed-rope system (double line), to carry 10 tons per hour	1,500	" 2,500
" " " 20 "	2,200	" 3,200

Prime Cost of Plant with Steel Structures.—The following table, by Mr. John H. Huntley, M.I.E.S., shows the pre-war standard amounts for aerial ropeways with no peculiar complications, using spiral construction ropes up to 20 tons capacity and locked coil ropes for 40 to 80 tons capacity, and represents the total cost of the plant erected. For lengths over 5 miles costs in proportion.

Capacity in Tons per Hour.	Length of Line in Miles.			
	½ Mile.	1 Mile.	2 Miles.	5 Miles.
Tons.	£	£	£	£
5 per hour	1,900	2,000	3,300	6,900
10 "	2,100	2,300	3,650	7,400
20 "	2,350	2,600	3,900	8,000
40 "	2,500	2,870	5,000	10,500
60 "	2,850	3,200	5,700	11,900
80 "	3,100	3,500	6,300	13,100

Working Costs per Day.—The following pre-war costs, by Mr. John H. Huntley, M.I.E.S., include depreciation, but exclude cost of driving, which varies extremely owing to the difference of height between stations, etc., and cannot be standardised.

Length in Miles.	Capacity per Day in Tons.					
	50 Tons.	100 Tons.	200 Tons.	400 Tons.	800 Tons.	1,000 Tons.
	s. d.	s. d.	s. d.	s. d.	s. d.	s. d.
½ mile	17 6	21 0	25 0	32 0	42 4	48 0
1 "	19 5	24 0	28 10	37 7	52 0	58 5
2 "	26 6	31 6	36 4	49 7	68 10	76 10
5 "	45 7	51 0	61 0	83 3	126 0	156 10

* All prices mentioned are pre-war figures unless otherwise stated; present rates (1925) about double.

Aerial Ropeway at Loch Leven, Argyllshire (1906).—Erected for the construction of a dam for water-power purposes. Length of line about 4⅕ miles. Arranged on the single-rope system, and has a mean gradient of 1 in 22·8, or a difference in altitude of 1,100 ft. against the loads. Three bends in the line, with a station at each bend, and including the power station and both terminals, there are six stations for loading and unloading. Eighty-six trestles, averaging 24 ft. high. Trestles, terminals, angle, and power stations of pitch pine. Driving power is from a Pelton wheel of 250 brake horse-power. Speed of line, 300 ft. per minute. Capacity, 700 to 1,000 tons per day, with 580 steel buckets, each having an individual load of 6 cwt., and spaced about 90 ft. apart. Twenty men are engaged in working the line. Total cost, including carriage, erection, and foundations, etc., complete, about 12,500*l.* or 2,600*l.* per mile.

Cost of operating per ton-mile, allowing for redemption in 3 years labour, and 10 per cent. on the labour account for supervision, was estimated at 2*d.*

Plant for Single-rope Fixed-grip System.—Prices vary greatly according to the ground passed over and the material transported, so the following figures are merely approximate. They are the rates for articles at manufacturers' works to which must be added the cost of packing and marking for export, about 4 per cent. overall, carriage, loading and unloading, and erection with concrete foundations, etc., as well as of motive power, which always differs. The value of timber structures would be about 15 per cent. less than that of corresponding structures in steel. From quotations received in August, 1922.

Description of Parts.	10 tons per 10 hrs'. line. £	25 tons per 10 hrs'. line. £	50 tons per 10 hrs'. line. £
1. Steel wire rope, trestle mountings, grips and carriers for a length not exceeding 1 mile—per mile	400	600	825
Ditto over 1 mile but not exceeding 3 miles in length—per mile	440	660	910
2. Driving and tension gears for a line not exceeding 1 mile	140	160	175
Ditto over 1 mile but not exceeding 3 miles in length	250	300	330
3. Mountings for each angle station giving any degree of deviation	70	80	90
4. Steel trestle structures, average about 16 per mile, height 20 ft., per trestle	18	22	20
5. Steel structures for terminal gears for a line not exceeding 1 mile	100	120	135
Ditto, ditto, for a line over 1 mile, but not exceeding 3 miles in length	160	180	200
6. Steel structures for angle stations, each	50	65	75

Example of Approximate Estimate.—To illustrate the method of estimating from the foregoing particulars the following example is given. The cost of a ropeway ¾ mile long to carry 25 tons per 10 hours with one angle station: steel trestles, and timber structures for terminal and angle stations. From quotations received in August, 1922:

	£	*s.*	*d.*
Steel wire rope, trestle mountings, grips, carriers, as No. 1—¾ of 600*l.* per mile	450	0	0
Driving and tension gears as per No. 2	160	0	0
Mountings for angle station as per No. 3	80	0	0
Steel structures for 12 trestles as per No. 4—22*l.* × 12	264	0	0
Timber structures for terminal gears as per No. 5—120*l.*, less 15 per cent. (18*l.*)	102	0	0
Timber structures for angle stations as per No. 6—65*l.*, less 15 per cent. (9*l.* 15*s.*)	55	5	0
	1,111	5	0
Packing and marking for shipment, 4 per cent.	44	9	0
Total cost of ropeway materials for ¾ mile	1,155	14	0

Add to the foregoing carriage, unloading, erection, foundations, and motive power.

Artesian Wells.

Artesian bored tube wells, including boring by the percussion, percussion hydraulic, or rotary methods, according to the sub-strata, supplying steel-socketed lining tubes with butt ends, flush-screwed, and special solid steel cutting shoe, and providing all materials, plant and labour, up to 100 ft. in depth; add 10 per cent. for every additional 10 ft. Telescoping the lining tubes

is obsolete, as they should be one continuous tier. Special sizes run up to 4 ft. and 6 ft. diameter. See also 'Tube Wells.'

Soil.	Tubes.	Per ft. deep.
In easy soils, such as earth and sand	3 in. to 4 in. external diameter	8*s.* to 10*s.*
	6 in. „ 9 in. „ „	13*s.* „ 18*s.*
In soft rocks, such as chalk or shale	3 in. „ 4 in. „ „	11*s.* „ 13*s.*
	6 in. „ 9 in. „ „	17*s.* „ 23*s.*
In hard rocks, such as basalt or sandstone	3 in. „ 4 in. „ „	17*s.* „ 20*s.*
	6 in. „ 9 in. „ „	25*s.* „ 32*s.*

London.—The charges of the Metropolitan Water Board for domestic supply are based upon 5 per cent. of the rateable value of property, and in the case of a large building, such as business premises or a bank, are out of all proportion to the water used. Charges of 200*l.* to 600*l.* per annum are common, and even 4,000*l.* has been paid. Roughly speaking, any building owner in London paying more than £120 a year for water will find it better to sink an artesian well. Boreholes over 1,000 ft. deep have been sunk in the London basin, and yield 100,000 gallons per hour. The flow is reliable, the water is of a low temperature, pure and soft (generally about 5° of hardness compared with 16° of the Water Board supply), leaves no deposit on pipes and boilers, and the cost is very small.

The capital outlay for many important buildings in London for an independent water supply, including sinking an artesian well and providing the pumping plant, where the quantity runs from 1,000 to 4,000 gallons per hour, varies from 1,500*l.* to 4,000*l.*

The cost of pumping artesian wells depends on the lift and power required, and may be as low as ¼*d.* per 1,000 gallons on a lift up to 400 ft., and is commonly 1½*d.* per 1,000 gallons for manufacturing purposes. Pumping by electric motors, with current at 1½*d.* per unit, will work out to about 2½*d.* per 1,000 gallons when the water is raised some 300 ft. from the borehole to the storage tanks above. The capital invested in a separate installation would thus be repaid in three to six years, leaving only the pumping costs to be considered as an annual expense, so that the value of artesian wells is apparent.

BORING.

Percussion boring by the ordinary 'English' method to depths of 500 ft. costs 10*s.* to 20*s.* per foot, advancing 2 to 6 ft. per 24 hours.

Rope boring for oil, salt, etc., holes 6 to 15 ins. diameter, 20 to 60 ft. per day, costs 2*s.* to 8*s.* per foot. Plant for a hole 2,000 ft. deep weighs 80 tons, and costs about 2,000*l.*

Diamond boring in hard rock, 5 ins. diameter, costs in this country 8*s.* per foot down to 500 ft., and 12*s.* to 18*s.* down to 1,500 ft. Advance 5 to 10 ft. per day. Bort 'diamonds' are 2*l.* to 3*l.* per carat for the softer rocks, and carbon 6*l.* to 12*l.* per carat for the harder ones. Boreholes above 6 ins. diameter are thus almost prohibitive for expense.

Chilled shot method for relatively large boreholes, 6 in. diameter, in hard ground, costs 10*s.* to 12*s.* per foot. It is slower but cheaper than diamond boring, and consists of chilled steel shot fed into a thick steel pipe notched at the lower end and rotated upon the rock to be pierced, with water forced down.

Actual Costs—The following are from practical pre-war experience :—	Per ft. *s.*	*d.*
Rope boring at Middlesbrough, 8 ins. diameter, to depths of 1,000 ft., at rate of 60 ft. per day	8	0
Ditto. in Pennsylvania and Ohio, 6 to 15 ins. diameter, at rate of 20 ft. per day, average contract price	6	0
Diamond boring in Scotland, 5 ins. diameter, to depth of 1,800 ft., advancing about 6 ft. per day	6	4
Ditto. in British Columbia, 2,200 ft. deep, at rate of 10 ft. per day	8	6
Ditto. in Nova Scotia, 2 ins. diameter, sunk by the Government in fairly hard ground to depths of 200 to 400 ft. in 1913, averaged	9	0
Ditto. in Victoria, also sunk by the Government, averaged in the coal measures in 1912	9	3
Ditto. ditto. in the harder rocks	14	0
Chilled shot 6 in. Government boreholes in Nova Scotia in 1913, averaged	10	6
Some important boreholes of the world—		
Bezuidenville, Transvaal, 5,800 ft.	42	0
Cznchow, Rybnik, Upper Silesia, 7,350 ft.	43	4
Paruschowitz, Silesia, 6,572 ft. (12 in. bore decreasing to 2¾ in.)	11	6
Schladebach, Prussia, 5,737 ft.	21	2

BREAKWATERS.

Breakwaters formed of large rough blocks of stone as a foundation with heavy masonry walls above, forming a harbour. Average width 300 ft., and average depth 50 ft. below low-water mark. 150*l.* to 300*l.* per foot run complete.

Alderney.—Composite type of rubble mound and upright wall above. Mound terminates 12 to 15 ft. below low water. 338 ft. wide at base and 36 ft. at top. 90 ft. mean depth of water. 259*l.* per foot run.

Algiers.—Mound type, with large random concrete blocks surrounding the rubble. 50 ft. mean depth of water. 122*l.* per foot run.

Bizerta.—Composite type, with wall built on caisson system. 58 ft. mean depth of water. 60*l.* per foot run.

Colombo.—South-west breakwater, 1874–85, is 4,212 ft. long, built of concrete blocks weighing 18 to 30 tons, on the sloping bond system, and cost 705,200*l.*, or 167*l.* per foot run. Extension to ditto as a further protective arm, 1907–12, is 1,800 ft. long, also of concrete blocks, and cost 380,000*l.*, or 211*l.* per foot run.

North-east breakwater, 1894–7, is 1,100 ft. long, and constructed as a rubble embankment; the north-west or island breakwater, 1900–6, is 2,657 ft. long, and made of concrete; the two together cost 500,000*l.*, or 133*l.* per foot run.

Total length of the four breakwaters about 9,770 ft., with five lighthouses on them, and total cost 1,585,200*l.*, or an average of 162*l.* per foot run. Depth of sea, 30 to 36 ft. at low water. Rise of tide at Ceylon is only 2 ft. Engineers, Sir John Coode, Son, and Mathews.

Dover.—Wall type, composed of concrete blocks weighing 26 to 40 tons, 82 ft. wide at base and 40 ft. at top. Depth of water, 61 ft. high; 42 ft. low. 415*l.* per foot run.

Holyhead.—Composite type, with very predominant mound of rough rubble stone, 400 ft. average width at base and 40 ft. at top. Sea and harbour walls built upon the mound. 54 ft. mean depth of water. 163*l.* per foot run.

Marseilles.—Mound type. Outer casing of concrete blocks, 25 tons each, and average thickness 14 to 20 ft. Inner casing of rubble stone, 2 to 5 tons weight, about 12 ft. thick. Rubble hearting, ½ to 2 tons stones, and 6 ft. thick. 35 ft. mean depth of water. Joliette section, 72*l.* per foot run, and new section, 109*l.* per foot run.

Naples.—Composite type. 93 ft. mean depth of water. 186*l.* per foot run.

Plymouth (1811–48).—Rubble mound with walls on top, nearly a mile long. Slope of 5 to 1 seawards. 360 ft. wide at base and 43 ft. at top. Average depth, 45 ft. below low-water mark. Absorbed 3,670,440 tons of rubble and 22,150 cubic yards of masonry. Engineer, Sir John Rennie. 250*l.* per foot run.

Portland.—Mound type with large rubble blocks and heavy masonry wall above, 270 ft. wide at base. The largest of its kind in England and in two portions—inner about 2,000 ft. long and outer over 6,000 ft., with 400 ft. opening between them. Depth of water, 58 ft. high; 51 ft. low. 6 million tons of stone used. Convict labour. Total cost, 1,250,000*l.* 140*l.* per foot run.

Maintenance.—This is less for walls than for rubble mounds, as the latter are greatly affected by wave action, and need constant repair. Cost varies according to situation and exposure, and rarely exceeded 1*l.* per foot run per annum, pre-war. For some time it averaged 1*s.* 3*d.* at Holyhead, 7*s.* at Geneva, and 13*s.* at Naples.

(See Section XXVII, p. 1469.)

BRIDGES.

Types.—(1) Arched, (2) Cantilever, (3) Girder or lattice, (4) Movable (bascule or lifting, rolling, swing, and transporter), (5) Pontoon (with barrels, boats, planks, etc.), (6) Suspension, (7) Trestle (with very high steel or wood framework piers), and (8) Viaducts or "land" bridges.

Costs include foundations, piers, abutments, approaches, footpaths, machinery, etc., complete.

Description.	Span.	Number of Spans.	Cost per ft. sup.
	ft. ft.		
Brick or masonry	50 to 100	Single	£1 to £2
	50 „ 100	Multiple	£2 „ £4
Ordinary concrete	30 „ 50	Single	15*s.* „ £1
	30 „ 50	Multiple	£2 „ £3
Reinforced concrete	50 „ 100	Single	10*s.* „ £1
	50 „ 100	Multiple	£1 „ £2
Steel bascule or lifting	50 „ 100	Single	£3 „ £5
	100 „ 200	Multiple	£5 „ £8
Steel girder or lattice	50 „ 100	Single	£1 „ £3
	50 „ 100	Multiple	£2 „ £5
Steel suspension	50 „ 100	Single	£1 „ £2
	100 „ 200	Multiple	£2 „ £4
Steel swing	50 „ 100	Single	£2 „ £3
	100 „ 200	Multiple	£3 „ £5

Brooklyn Bridge (1870–83).—Wire cable suspension bridge over the East River, connecting New York with Brooklyn. 5,990 ft. total length, including 1,596 ft. central span from tower to tower, two spans of 930 ft. from the towers to anchorage on either side, and the approaches of ironwork and masonry, 1,563 ft. on New York side and 971 ft. on Brooklyn side. Width 85 ft., divided into five passage ways for vehicles, trams, and foot passengers. Clear height above high water 135 ft. in centre and 118 ft. at towers, giving a free passage to shipping. Towers 277 ft. above high water, upon rock foundation 80 ft. below surface of river and 40 ft. beneath its bed. Supporting the spans are four cables nearly 16 ins. diameter, and 3,758 ft. long, with anchorages of solid stone masonry weighing 60,000 tons each, and rising 90 ft. above river's edge. Each cable contains 5,282 galvanised steel wires in 19 separate strands, of 278 lengths, and each strand has over 200 miles of continuous wire. Wires laid parallel, not twisted, with spiral wire wrapping. Deflection of cables between towers is 128 ft. Engineer, John A. Roebling. Total cost, including approaches, 3,100,000*l.*, or 518*l.* per ft. run, or 6*l.* per ft. sup.

Forth Bridge, Scotland (1883–90).—At South Queensferry, near Edinburgh. Steel latticework, with two main cantilever spans 1,710 ft. each, and 24 land spans, 42 to 688 ft. each. Each cantilever 690 ft. long, united by a girder 250 ft. span. The steel towers supporting the cantilevers are 361 ft. high, and the steel tubes of both are 12 ft. diameter at base, tapering to extremities. 50,960 tons of steel employed and 6½ millions of rivets. Complete length, 8,100 ft., and with approaches, 8,300 ft.; width, 30 ft.; 145 acres of surface to be painted. Double line railway. Height of railroad, 152 ft. above high water. Main piers of masonry, and concrete foundations in rock, 70 ft. below high water. Central pier of granite standing on the islet of Inchgarvie. Engineers, Sir John Fowler and Sir Benjamin Baker. Contractors, Sir Wm. Arrol & Co. Total cost, including approaches, 1,700,000*l.*, or 25*l.* per ft. run, or 7*l.* per ft. sup.

Gôkteik Viaduct (1901).—In the Shan States, Upper Burmah, the viaduct forming part of the railway where it crosses a deep wide valley about 80 miles from Mandalay, and runs on to Kunlon at the Chinese frontier. The second most lofty steel trestle bridge in the world, but for combination of height, length, and weight of material easily the first. It is straight for 1,638 ft. at the centre, with terminal curves of 800 ft. radius, 341 ft. and 281 ft. long respectively. Total length between abutments, 2,260 ft. There are 15 trestles or skeleton towers, varying from 250 ft. to 320 ft. in height, 10 spans of 120 ft., and 7 spans of 60 ft., or 17 spans altogether, formed with lattice or plate girders. 5,000 tons of metal, and 200,000 rivets. All the metal parts, some 230,000 pieces, were prepared in the United States, shipped 10,600 miles, and transported 460 miles up country by the Burmah railway, where they were re-assembled and put up without a hitch. A single track was first laid, but space was left for a second when the traffic required it. Total cost, 61,000*l.*, or 27*l.* per ft. run, or 3*l.* 10*s.* per ft. sup.

Holyhead, Britannia Tubular Bridge (1845–50).—Across the Menai Straits. Continuous double tube of wrought-iron plates, each tube 15 ft. wide by 23 ft. high at ends, and 30 ft. at centre, with one railway line in each. Two main spans of 460 ft. each, two smaller spans of 230 ft., and two shore spans of 65 ft., or a total length of 1,510 ft. Each tube weighs 4,680 tons, and is fixed 100 ft. above high water. Two abutments, and three masonry piers or towers, the highest of which is 230 ft. Complete distance, with approaches, 1,560 ft. Engineers, Robert Stephenson, assisted by Sir Wm. Fairbairn and Professor E. Hodgkinson. Total cost, including approaches, 608,000*l.*, or 390*l.* per ft. run, or 13*l.* per ft. sup.

Kingston Bridge, Surrey (1825–8).—Brick and stone. Five elliptical arches: middle arch 60 ft. span, other arches 56 ft. and 52 ft. span. Ratio of piers to spans, 1 : 6. Bridge, 382 ft. long and 25 ft. wide. Bridge itself, 26,800*l.*; approaches and other works, 13,200*l.* Total cost, 40,000*l.*, or 105*l.* per ft. run, or 4*l.* per ft. sup.

London Bridge (1824–31).—Stone bridge of five elliptical arches over the Thames and of handsome design, connecting the City of London with the borough of Southwark, and replacing the 12th century stone bridge. Centre span 152 ft., rising 30 ft. above Trinity high-water mark, arches on each side 140 ft. spans, and abutment arches 130 ft. Total length 1,005 ft., and 56 ft. outside width. Two centre piers 24 ft. thick, exterior stones of granite and interior half Bramley Fall and half Painshaw, Derbyshire; granite voussoirs. General depth of foundations 30 ft. below low water. Engineer, John Rennie, and completed by his son Sir John Rennie. Contractor's tender for the bridge alone was 425,081*l.*, but actual cost was 1,458,310*l.*, or 1,451*l.* per ft. run, or 26*l.* per ft. sup.

Newcastle High-level Bridge (opened 1849).—Example of a true bowstring arch in which there is no cross bracing, with six spans of 125 ft. each. Total length 1,373 ft., and 37 ft. external width. Superstructure is supported on five intermediate piers and eight land piers, four at each side, latter with arched abutments. Height of soffit above high-water, 83 ft. Arched ribs of cast iron and ties of wrought iron. 4,728 tons of cast iron and 321 tons of wrought iron were employed. A carriage roadway passes underneath the railway, the bridge supporting both. Engineer, Robert Stephenson. Total cost, 243,000*l.*, or 177*l.* per ft. run, or 5*l.* per ft. sup.

Niagara Suspension Bridge (1852–5).—Connects the United States with Canada. A wire-rope suspension bridge for road and railway, with a single span of 821 ft., centre to centre of piers and 245 ft. above the water. Superstructure is a hollow rectangular box, 24 ft. wide × 18 ft. deep, on the top of which the railway is laid, while the bottom forms a roadway for public traffic, both floors being constructed of timber beams, etc. Railway floor is suspended from two wire cables, 10 ins. diameter, at intervals of 5 ft., and the lower floor by two similar cables. 120 stays. Two masonry towers at each end of the bridge, 60 ft. high, 15 ft. square at base, tapering to 8 ft. square at top, and pierced by an arch. Anchor chains embedded in masonry 7 ft. × 3 ft., and 25 to 35 ft. deep. Engineer, John A. Roebling. Total cost, 80,000*l.*, or 97*l.* per ft. run, or 4*l.* per ft. sup. This suspension bridge was replaced by a steel arch bridge in 1897.

Tower Bridge, London (1890–4).—Steel, with two fixed shore suspension spans 270 ft. each, and a lifting central span of 200 ft. Two large steel towers encased with stone, with two bascules or drawbridges in the centre and connected at top by a high-level footbridge, 140 ft. above high water. Bascules weigh 1,000 tons each, and are raised and lowered by hydraulic machinery which is contained in the chambers of the piers supporting the towers, each pier being 180 ft. long × 70 ft. wide. Staircases and hydraulic lifts are provided in the towers for foot passengers crossing the high-level bridge when the bascules are raised for the passage of shipping. Complete length, with approaches, 2,980 ft. Width of fixed spans between parapets, 60 ft., and breadth across centre span 50 ft. Engineer, Sir John Wolfe Barry. Sir Horace Jones, the City Architect, designed the architectural details. Contractors: Sir John Jackson for foundations; Sir Wm. Arrol & Co. for steelwork; and Sir W. G. Armstrong & Co. for hydraulic machinery. Total cost, including machinery and approaches, 903,000*l.*, or 303*l.* per ft. run, or 5*l.* per ft. sup.

Westminster Bridge, London (1853–62).—Road bridge over the Thames, with cast and wrought iron arches of 120 ft. span and 20 ft. high. 1,160 ft. long and 83 ft. wide. Engineer, Thomas Page. Contractors, Messrs. Mare. Total cost, 235,000*l.*, or 203*l.* per ft. run, or 2*l.* per ft. sup.

Suspension Bridges.

Estimated costs by a well-known firm of steel manufacturers of strong steel wire rope suspension bridges of large power, designed to carry 15-ton traction engines with wagons in line on the bridge floor, the prices being for the whole of the iron and steel work, including lattice piers surmounted by cast-iron saddles for the ropes to run over, all bolts and nuts, holding down bolts, steel rod suspenders, open-steel parapets, high tension steel cables, steel cross girders to support decking, steel wind ties under floor, etc., ungalvanised but painted two coats before despatch, delivered f.o.b., London or Liverpool, or to railway stations in England; supplied only, and exclusive of timber floor, foundation work, and erection. Pre-war rates. If a concrete or asphalte floor is required the prices will be subject to an increase, owing to the additional strength necessary and the greater weight put on the structure. The span is centre to centre of piers, and the feet super. for area unit price, have been reckoned accordingly.

Span.	Width.	Area.	Total Price.	Price per Foot Super.	Weight of Steelwork.
Ft.	Ft.	Ft. Sup.	£	*s.* *d.*	Tons.
50	19	950	565	11 11	31
75	19	1,425	785	11 0	44
100	19	1,900	945	9 11	53
125	19	2,375	1,115	9 5	60
150	19	2,850	1,275	8 11	66
175	19	3,325	1,430	8 7	75
200	19	3,800	1,575	8 3	81
225	19	4,275	1,740	8 2	91
250	19	4,750	1,880	7 11	100
275	19	5,225	2,065	7 10	110
300	19	5,700	2,230	7 10	118

The prices may therefore vary from about 8*s.* to 12*s.* per ft. sup. If erected complete, including timber floor and concrete, stone, or brick foundations or abutments, and anchorages, the costs would be at least double the foregoing. Narrower bridges, down to 3 ft. wide, for lighter loads, such as foot traffic, cattle, mules, horses and carts, would be of reduced construction and correspondingly cheaper.

Actual costs of steel wire-rope suspension bridges, delivered and erected, including steel piers, wire ropes, suspension bands, and timber for floor, but exclusive of any foundation work or

anchorages. Pre-war rates. The span is centre to centre of piers, and the feet super. for area unit cost have been reckoned accordingly as before.

Locality.	Load.	Span.	Width.	Area.	Total Cost.	Cost per F.S.
		Ft.	Ft.	Ft. Sup.	£	*s.* *d.*
Bournemouth, across Alum Chine	Donkey carts and bath chairs	230	6	1,380	590	8 7
Derby sewage works	Foot traffic	86	3	258	165	12 9
Dryburgh, across the Tweed, near Melrose Abbey	Foot traffic	260	6	1,560	540	6 11
Linley, over the Severn. Two approach spans in addition, making a total span of 390 ft.	A row of 10-ton carts	213	12	2,556	1,700	13 3
Llandilo	Foot traffic	144	5	720	220	6 1
Llangollen	Foot traffic	146	3	438	190	8 8
Rhayader, for the Birmingham Corporation Waterworks	Cart traffic	110	10	1,100	450	8 2
Shrewsbury. Two approach spans of 30 ft. each in addition, making a total span of 210 ft.	Light vehicular traffic	150	8	1,200	950	15 10
Swalwell, over the Derwent	Foot traffic	125	4½	562	285	10 2
Warrington	Foot traffic	183	6	1,098	430	7 10
Wrexham, across the Dee.	Row of loaded haycarts	130	10	1,300	670	10 4

The average rate was therefore about 10*s.* per ft. sup. If erected complete, including foundation work and anchorages, the costs would be at least double foregoing.

Bridges of Concrete.

Coulouvrenière Bridge, Geneva (1895–6).—Across the Rhone, 351 ft. wide, and total length of bridge over the abutments 492 ft. Width between parapets 61 ft. 4 ins., two footways 12 ft. 6 ins. each, with a carriageway 36 ft. 4 ins. between the kerbs. Two large arches with spans 131 ft. 3 ins., and rise of 17 ft. 6 ins. Arches 3 ft. 3 ins. thick at both springings and centre, about 4 ft. 6 ins. at the haunches, and steel pivoted. Two smaller arches, 35 ft. 5 ins., and 39 ft. 4 ins., but are not pivoted, being elliptical. Very handsome bridge. Arches, spandrels, 9 spandrel walls, 2 ft. thick, 12 in. top table, and filling, all of concrete, 1 to 4¼, 6, 7, and 8. Piled abutments. Facing of spandrel walls, columns, cornice, and parapet of stone. Wooden centres were used, with sand boxes for adjusting and striking. Total cost, 68,000*l.*, or 138*l.* per ft. run, or 2*l.* 5*s.* per ft. sup. of roadway and footpaths. Cost per cubic yard, including centering and scaffolding, was 3*l.* 2*s.* 3*d.*

Eyach Bridge, Hohenzollern (1895).—Designed by Herr Max Leibbrand, of Sigmaringen. A single span of 98 ft. 5 ins., with a rise of 9 ft. 10 ins. Concrete arch and table, 1 to 7½, and foundations to abutments, 1 to 9, which are piled. Pivots or joints made of granite instead of iron or lead. Bridge is 143 ft. long, 12 ft. 6 ins. total width, with roadway 7 ft. 6 ins. wide, and each footpath 2 ft. 6 ins. The footpaths overhang the arch on either side and were formed of old iron rails. Plain iron railing as parapet. Cost, 900*l.*, or 6*l.* per ft. run, or 10*s.* per ft. sup.

Kirchheim Bridge, Württemburg (1897).—Over the Neckar, which is 361 ft. wide at this point, with 230 ft. of foreshore, or a total of 591 ft. Designed by President von Leibbrand, chief engineer to the State of Württemburg. Length of bridge from outside to outside of abutments, 592 ft., and space between parapets 17 ft. 8 ins., including road, 12 ft. 8 ins., and two footways, 2 ft. 6 ins. each; open iron parapets. Four spans of concrete arches, 124 ft. 8 ins. each, with a rise at the centre of 18 ft. Thickness of arch at crown, 2 ft. 8 ins., increasing to 3 ft. at springing. Concrete piers 7 ft. 6 ins. thick at springing level, faced with stone at water level; cutwaters also faced with stone. Concrete in arches and abutments, 1 to 7½, spandrel walls, tables, etc., 1 to 9, and foundations for piers, 1 to 4. Concrete on face was tooled and coloured, and concrete in piers rendered 2 ins. thick with 1 Portland cement and 2 sand. Lead joints in the centres and springings of arches 6 to 7 ins. wide, bedded and recessed in stone. Screw jacks were used for striking the centres in place of folding wedges or sand boxes. Cost, 7,000*l.*, or 12*l.* per ft. run, or 13*s.* 5*d.* per ft. sup. of bridge table. Approaches, 2,250*l.* in addition.

Munderkingen Bridge, Württemburg (1893).—Over the Danube. Designed by President von Leibbrand. One span only of 164 ft., and rise 16 ft. 5 ins. Thickness of arch at centre 3·28 ft., at springing 3·61 ft., and at haunches 4·26 ft. The first concrete bridge where steel pivots on bearing boxes were used, one set at each abutment and one set at the crown. Internal and external spandrel walls, abutments, horizontal and intermediate tables, cornice, and arch itself, were of concrete, 1 to 7½, and tinted. Spandrel face of limestone, and ornamental open iron parapet. Cost of bridge, including piled abutments, 3,600*l.*, or 21*l.* per ft. run, or 13*s.* 6*d.* per ft. sup. of road and footway surface. Approaches, 1,000*l.* in addition.

Neckarhausen Bridge, Hohenzollern (1900).—Over the Neckar. Designed by Herr Max Leibbrand, of Sigmaringen. The handsomest concrete bridge in Germany, the concrete being coloured, and no stone used. A single concrete arch of 164 ft. clear span, with a rise of 15 ft. Arch ring 2 ft. 10 ins. thick at the centre, 3 ft. at the springing, and 4 ft. at the haunches. The arch is tapered on plan, being 1 ft. 8 ins. wider at the springing than at the centre. Concrete spandrel columns and arches over, instead of solid spandrel walls and haunches, thus reducing both material and dead load. Arches pivoted with steel pins and cast-iron brackets or bearings, and those carrying roadway were strengthened with iron rails built into the top and abutments. Concrete in arch 1 to 7½, faced with ⅝-in. spalls of limestone. Voussoirs, cornice, etc., were coloured. Width of macadam roadway 13 ft., and overhanging footpaths 2 ft. 6 ins., which is a cheap method. Centering was supported on temporary piles, with screw jacks for striking. Cost, 3,000*l.*, or 17*l.* per ft. run, or 19*s.* 5*d.* per ft. sup. Long approaches, 5,000*l.* in addition.

Bridges of Reinforced Concrete.

Spans, 50, 75, or 100 ft. External width, including parapets, 25 ft. Height, from mean water level to underside of elliptical arch, 13 ft. 15*s.* to 30*s.* per ft. sup.

Items.	Cost.		
	50 ft. Span.	75 ft. Span.	100 ft. Span.
	£	£	£
Excavations	70	111	184
Concrete	251	462	667
Centering	129	240	341
Reinforcing Steel	104	194	277
Preliminaries 10 per cent.	55	100	147
Contractors' Profit, etc., 15 per cent.	91	166	242
Total Cost	700	1,273	1,858

Alexandra Bridge, Pietermaritzburg (1914–15).—Reinforced concrete on the Kahn system. 170 ft. long × 30 ft. wide between the parapets, with two 5-ft. footpaths cantilevered over a 20-ft. roadway. Central arch 75 ft. span, and a half arch 38 ft. span at each end. Cost, including 5 per cent. for designs and supervision, 5,906*l.* for the bridge and 4,008*l.* for the approaches = 9,914*l.* total. 52*l.* per ft. run, or 2*l.* per ft. sup.

Brivio Bridge, Italy (1913–17).—Over the river Adda, and gives access to the railway station of Cisano Bergamasco. Entirely constructed of reinforced concrete, 444 ft. long and 30 ft. wide, with a 24 ft. roadway flanked by two raised footpaths, each 2 ft. 7 ins. wide, with edges of L irons. The roadway is about 26 ft. above the average level of the river, and suspended from three reinforced concrete arches overhead. Span of centre arch 177 ft., and of side arches 144 ft., all being supported on two massive concrete pillars and shoulders, each 43 ft. × 13 ft., built on a group of 48 steel-shod concrete piles made on the Considère system, 14 ins. square, and driven 43 to 53 ft. through the bed of the river by a steam hammer weighing 4 tons. Normal load on each pile averages 35 tons, uniformly distributed by a superimposed concrete slab 3 ft. thick. Foundations protected by pitch pine shuttering 5 ins. thick. Sole of roadway 5 ins. thick, covered with asphalt and a layer of concrete and gravel on top, with 12 in. × 30 in. transverse beams underneath attached to 11 in. × 24 in. vertical bars and to 18 in. × 40 in. longitudinal external beams. Cast steel rollers for expansion. Parapet is of cast ironwork. Bridge designed to carry a double-track electric tramway, a steam roller of 22 tons, and a dense crowd of people calculated at 10 cwt. per square yard. Total cost, 20,000*l.*, or 45*l.* per ft. run, or 30*s.* per ft. sup.

Chatellerault Bridge, France (1900).—Across the river Vienne, and is formed entirely of ferro-concrete on the Hennebique system. Centre span 164 ft. and two side spans 135 ft. each, with rises of respectively 16 ft. and 13 ft., and a width between the parapets of 26 ft. 3 ins., excluding two cantilevered footways which overhang 3 ft. 5 ins. Spans of four arched concrete ribs, 35 ins. deep × 19 ins. wide at springings, tapering to 9 ins. square at the soffit, and extrados connected together by an arched table. Roadway and footpaths supported by spandrel pillars, 8 ins. square, and longitudinal concrete beams, the top table being 10 ins. thick at the centre, tapering to 5 ins. at kerb. The bridge only weighs 250 lbs. per ft. sup. Cost, 8,000*l.*, or 18*l.* per ft. run, or 12*s.* 6*d.* per ft. sup.

Loughor Bridge, Glamorganshire (1920–23).—Spans the tidal estuary of the river Loughor, and replaces the old timber trestle structure. The new bridge is of reinforced concrete, from a design by Messrs. L. G. Mouchel and Partners, carried out by the Yorkshire Hennebique Contracting Co., Ltd. Length, 720 ft. between the abutments, divided into 18 spans of 40 ft. each. Width, 36 ft. between the parapets, providing two footways, 5 ft. wide, and a carriage-way of 26 ft. between the kerbs. Piers rest on reinforced concrete piles, 15 ins. square, driven into the bed of the river to various depths of 5 ft. to 37 ft. Four piles to each pier, each pile being encased in a reinforced concrete cylinder, 1 ft. 9 ins. diameter, cross-braced with reinforced concrete tie-beams, 10 ins. × 14 ins. Main longitudinal beams, 12 ins. wide × 2 ft. 8 ins. deep in the centre; secondary beams, 7 ins. × 18 ins. Four main or longitudinal beams and 12 secondary or cross beams to each span. 5½ ins. reinforced concrete decking, covered with 2 ins. cushion of sand and finished with 4 ins. of 'Tarmac' roadway. Ducts, 18 ins. × 9 ins., left under footpath concrete flagging to accommodate electric cables. Parapet of pierced concrete panels, with moulded handrail. Abutments have reinforced concrete wall supporting the ground behind. Steel reinforcement was of plain round steel bars, $\frac{3}{16}$ in. to 1⅛ in. diameter, and the bridge was built in half-widths, so as not to interrupt the traffic. It was designed to carry a normal working super. load of 120 lbs. per square ft., and a rolling load of 48 tons. Total cost, excluding approaches, 56,700*l.*, or 79*l.* per ft. run, or 2*l.* 2*s.* 7*d.* per ft. super.

Pontypridd Bridge (1908).—Over the river Toll. Reinforced concrete on the Hennebique system, with the two piers on reinforced concrete piles. Total length 170 ft., and width 30 ft. Central river span 117 ft. Total, 3,600*l.* 21*l.* per ft. run, or 14*s.* per ft. sup.

Terralba Bridge, Italy (1916).—Part of a scheme for enlarging the Genova Brignole Station. It replaces about 600 ft. of the Terralba highway connecting St. Martino with St. Fruttuoso. Total length of bridge, including approaches, is 750 ft.; width 45 ft., including two footways each 5 ft. wide. Constructed of reinforced concrete and has six spans, four of 61 ft. and two of 58 ft., each span being built in three bays across. Part of the inclined approach was also formed in six spans, each of 35 ft. and three bays across, the remainder of the plane being constructed of massed work between supporting walls. Subsoil was a deep bed of soft, marshy clay, which prohibited piling and required a specially light foundation formed by 1 per cent. reinforced concrete rafts, the reinforcement being carried up into the pillars of the bridge. The rafts were supported on two pinewood piles per square yard, each 20 ft. long by 10 ins. wide, and tops coated with cement. Volume-ratio of reinforcement in superstructure was 1·8 per cent. to the gravel concrete. Total cost, 18,000*l.*, or 24*l.* per ft. run, including approaches, or 12*s.* 5*d.* per ft. sup. of concrete, including the foundation, and 6*s.* 8*d.* per ft. sup. of road and footpath.

Warrington Bridge (1913).—Over the river Mersey. Largest single-span reinforced concrete bridge in England, on the Considère system. River walls and abutments also of reinforced concrete. Clear span 134 ft., width 80 ft. between parapet walls, and ten parabolic ribs supporting upright and cross beams on which rest 6½ in. floor slabs. Roadway has wood-block paving, and footpaths have concrete slabs. Total cost, including approaches, 24,000*l.* or 34*s.* per ft. sup. ditto.

Canals.

The total length of canals for inland navigation in the United Kingdom is 4,673 miles (3,641 in England and Wales, 184 in Scotland, and 848 in Ireland). 1,144 miles are owned by the railway companies, and 219 controlled by them. An ordinary inland canal in this country is 25–30 ft. wide at bottom, 40–45 ft. wide at water level, and 4–5 ft. deep. Canal boats are 70–75 ft. long and 7–8 ft. wide; barges are about the same length, but double the width, *i.e.* 14–15 ft. For maps and towns, etc., see the *Handbook on Canals*, with map, issued by the Canal Control Committee (Board of Trade), and obtainable from H.M. Stationery Office, Kingsway, London, W.C. 2, price 6*d.* net, or 8*d.* post paid. (November, 1918.) Total paid-up capital was 47,550,000*l.*, and the cost varied from about 5,000*l.* to 20,000*l.* per mile.

In 1905 the constructional cost of new canals in Great Britain, 40–45 ft. wide at bottom, 80–85 ft. wide at water level, and 8 ft. deep in centre, with locks 230 ft. × 22 ft. and 6½ ft. draught of water over sills, suitable for two lighters of 250 tons carrying capacity, was estimated at 30,000*l.* per mile. The cost of improving existing routes to reach the same standard was similarly reckoned at 15,000*l.* per mile.

In France, in 1870, there were 3,000 miles of canals and 2,000 miles of canalised rivers. The average cost of the French canals up till then was 11,600*l.* per mile, and of the canalised rivers, 4,800*l.* per mile. Present length, 7,500 miles.

Barge or Boat Canals.

Basingstoke Canal (1794–96).—From Basingstoke, Hampshire, to the river Wey Junction Canal, Surrey. Length, 37 miles, including 29 locks. Total cost, constructional works only, 170,000*l.* or 4,600*l.* per mile.

Bridgewater Canal (1759–61).—In Lancashire; originated by the Duke of Bridgewater to bring coal from his mines on the Worsley estate to Manchester, but it was later extended to the Mersey. First length was only 10 miles, but complete length 38 miles. 50 ft. wide and 5½ ft. deep, with vertical stone walls instead of banks. The Barton aqueduct carried the canal over the river Irwell, at a height of 39 ft. Engineer, James Brindley. (The Bridgewater Canal was purchased by the Manchester Ship Canal Co. in 1887). Total cost, constructional works only, 235,000*l.*, or 6,180*l.* per mile.

Dortmund and Ems Canal (1890–1900).—From Dortmund to the North Sea at Emden. Part of the 157 miles total length includes canalisation of the river Ems. Bottom width, 59 ft., 98 ft. at water level, and depth, 8 ft. Works include 1 canal lift, 3 masonry aqueducts, 185 bridges, and 20 masonry locks, 220 ft. long each. Artificial canal portion cost 29,000*l.* per mile, and river canalisation portion, 14,000*l.* per mile. The locks were 15,000*l.* each, and the weirs 8,500*l.* each. Total cost, 3,970,000*l.*, including 400,000*l.* for land.

Cost per mile of total length, including land . . . . 25,286*l.*
" " " " constructional works only . . 22,740*l.*

Ebbing Canal.—In Holland. Length, 28 miles. Total cost about 212,200*l.*, or 7,580*l.* per mile.

Grand Junction (begun, 1790).—From the Oxford Canal at Bramston, Northamptonshire, to the Thames at Brentford, Middlesex. Width at bottom, 24 ft., and 36 ft. at water level. The main line is 93 miles long, but the total length, with branches, is 140½ miles (189 by Whitaker). Cost per mile, including land, etc., 19,500*l.*

Ulster Canal (1826–41)—Unites Lough Neagh with the upper Lough Erne, and extends from Charlemont, Co. Armagh, on the river Blackwater (which is navigable from Charlemont to Lough Neagh), passes Caledon, Monaghan, and Clones, and joins Upper Lough Erne, Co. Fermanagh, near Belturbet. Length, 47 miles. Total cost, constructional works only, 200,000*l.*, or 4,255*l.* per mile.

Worcester and Birmingham Canal (1791).—Connects these towns, and joins the Severn at the former. Runs through a tunnel 500 yards long, and three shorter tunnels. All are 18½ ft. wide, 7 ft. deep, and 18 ft. high. Length, 30 miles. Original cost per mile, 20,000*l.*

Irrigation Canals.

For irrigating large tracts of land for growing cotton, rice, sugar, wheat, etc., especially in America, Australia, Egypt, and India. The cost varies according to geographical features, nature of ground, available water supply, size of main canal, number of branches, distributing channels, and subsidiary works. In India the costs are approximately—

5,000*l.* to 10,000*l.* per mile of canal and main branches.
2*l.* to 3*l.* per acre of land irrigated.

Agra Canal (opened 1874).—In India, and draws its water supply from the Jumna at Okhla, ten miles below Delhi, irrigating 380,000 acres. The main and branch canals total 110 miles, and the distributing channels 600 miles. Total cost, including all works, 800,000*l.*

7,270*l.* per mile of canal and main branches.
2*l.* 2*s.* per acre of land irrigated.

Cavour Canal (begun 1862).—In Italy, and starts from the river Po, not far from Turin, and terminates in a junction with the river Tessin above Novara. Length, 51 miles, with a total fall of 71 ft. The summer discharge of the Po being found insufficient, a branch canal was constructed for bringing a supplementary supply from the Dora Baltea, which rises from the glaciers of the Alps and possesses a large discharge in the summer when the Po is low. Total cost, 4,104,000, or 80,470 per mile of main canal.

Ganges Canal (opened 1854).—The largest irrigation work in India, and waters the district between the Ganges and the Jumna. Designed by Sir Proby Cautley. The canal with its main branches is about 650 miles long, and can irrigate an area of 1,205,000 acres. It was remodelled about twelve years later. Total cost up to 1878 was 3,055,000*l.*

4,700*l.* per mile of canal and main branches.
2*l.* 11*s.* per acre of land irrigated.

Lower Ganges Canal (1870–90 approximately).—An extension to supplement the original foregoing canal. Designed for a total length of 582 miles. Irrigates 2,500,000 acres. Total cost about 4,500,000*l.*

7,730*l.* per mile of canal and main branches.
1*l.* 16*s.* per acre of land irrigated.

Upper Swat Canal.—In India, along mountainous country at the Malakand hills. Length, 150 miles, and irrigates 450,000 acres. Works include a tunnel, 11,235 ft. long by 18 ft. wide and 13 ft. high, seven shorter tunnels totalling one mile, 167 aqueducts across ravines, 20 to 100 ft. deep, a weir 700 ft. long, stop-dam, pitched channel, etc. Total cost about 1,300,000*l.*

8,670*l.* per mile of canal and main branches.

2*l.* 18*s.* per acre of land irrigated.

Ship Canals.

Large waterways as formed for ocean-going shipping, complete with channels, locks, docks, machinery, entrance breakwaters, etc.; construction works only, and excluding promotion, purchase of land, compensation, or legal charges:

100,000*l.* to 500,000*l.* per mile of actual canal.

Amsterdam Canal (1865–76).—Connects Amsterdam and the Zuyder Zee with the North Sea *via* Lake Y and Wyker Meer, and across a narrow neck of sand-hills in a westerly direction. Works comprise a dam 4,462 ft. long, with maximum bottom width 147 ft. and top width 13 ft., shutting off Lake Y from the Zuyder Zee. There are five large locks, six sluiceways, three swing-bridges (two railway and one roadway), and a harbour of 260 acres at the North Sea entrance, protected by two rubble stone breakwaters, 5,070 ft. long each, with pier on top formed of concrete blocks, 6 to 12 tons each. Canal is 16½ miles long, 88½ ft wide at bottom, 186 ft. at water level, and 23 ft. deep (now increased to 30 ft.). 21,000,000 cubic yards of soil and mud were excavated and dredged and 13,000 acres of land reclaimed. The sale of the latter realised about 70*l.* an acre, or a total of some 910,000*l.*, which mitigated the engineering cost. The largest type of dredger used could deposit 1,300 cubic yards of material on the banks in twelve hours, at 2*d.* per cubic yard. Permanent pumping machinery was installed for draining the adjacent lands into the canal and out again into the sea. Engineers, Sir John C. Hawkshaw and Mr. Dirke. Contractors for the whole of the works, Messrs. Henry Lea and Son. For full details see paper by Mr. Harrison Hayter read at the Institution of Civil Engineers in 1880, and printed in the *Proceedings*, vol. lxii. p. 1.

	Total.	Per Mile.
Constructional works only . . .	2,600,000*l.*	157,580*l.*
Other expenditure and charges . .	400,000*l.*	24,240*l.*
Whole cost	3,000,000*l.*	181,820*l.*

Caledonian Canal (1803–23).—From Inverness to Fort William, along the Great Glen of Scotland, and connects Inverness Firth with Loch Eil, having Lochs Ness (22 miles), Oich (6 miles), and Lochy (10 miles) in between. The summit level of 102 ft. is overcome by 28 locks, 14 on either side, each about 170 ft. long × 40 ft. wide; 23 miles of artificial or canal navigation in four stages, and 38 miles of natural lake navigation through the foregoing three lochs, the total distance between extremities being thus 61 miles. Canal is 50 ft. wide at bottom, 120 ft. at water level, and 17 to 20 ft. deep, for vessels up to 600 tons burden. Engineer, Thomas Telford. Total cost including land, 1,311,270*l.*, or 57,010*l.* per mile of actual canal length of 23 miles.

Corinth Canal (1882–93).—Across the isthmus of Corinth, between Gulf of Corinth and Gulf of Aegina, in Greece, and mostly through solid rock with very deep cutting. The neck of land rises in the centre to 286 ft. above the bottom of the canal. Bottom width, 72 ft., and average depth, 26 ft. No locks. Length, 4 miles. Entrances at each end protected by solid jetties built out into the sea. Greek engineer, Matsos. Total cost, 1,400,000*l.*, or 350,000*l.* per mile.

Cronstadt and St. Petersburg Canal (1877–90).—Starts from the Neva and goes south-west for about 2 miles, when it curves and proceeds in a straight line to Cronstadt. Average width, 240 ft., and depth, 20 ft. No locks. Total length, 16 miles, including 10 miles bay channel and 5 miles canal proper. Costs per mile are based on the total length of 16 miles.

	Total.	Per Mile.
Constructional works only . . .	1,240,000*l.*	77,500*l.*
Other expenditure and charges . .	760,000*l.*	47,500*l.*
Whole cost	2,000,000*l.*	125,000*l.*

Elbe and Trave Canal (opened 1900).—In Germany. Width at bottom, 72 ft., and depth, 10 ft. Length, 41 miles. Total cost, 1,170,000*l.*, or 28,540*l.* per mile.

Kiel Canal (1888–95).—Also known as the Kaiser Wilhelm Canal, or the Baltic and North Sea Canal, connecting Kiel in the Baltic to Elbe in the North Sea. Mostly through marshes or shallow lakes and river valleys, with tidal waterway throughout. Original dimensions: bottom width, 72–85 ft., surface width, 190–226 ft., and depth, 28–30 ft. (since increased to 150 ft., 335 ft.,

and 45 ft., respectively). Total excavation, 106,000,000 cubic yards. Two entrance locks, originally 492 ft. long × 82 ft. wide × 32 ft. deep over sill (now enlarged to 1,083 ft. × 148 ft. × 45 ft., and constructed in concrete, each lock having three pairs of caissons dividing the chambers into lengths of 725 ft. and 330 ft.). The original canal was completed in 1895, and the works for broadening and deepening in 1914. Breakwaters at each end. Length, 61 miles.

	Total.	Per Mile.
Original cost up to 1895, including land purchase	7,800,000*l.*	127,870*l.*
Enlargements and reconstructions up to 1914	11,200,000*l.*	183,605*l.*
Whole cost	19,000,000*l.*	311,475*l.*

Manchester Canal (1887–94).—Connects Manchester with Eastham, the Mersey port of Liverpool. Fifteen miles of canal proper, and 21 miles tidal waterway, or 36 miles total. Canal averages 120 ft. wide at bottom, 170 ft. at water level, and 26 ft. minimum depth (now increased to 28 ft.). Four sets of locks, with an average lift of 15 ft. each, thus raising the water level of the canal at Manchester to 60 ft. above mean sea-level at Liverpool. Capacity for 9,000 ton vessels, and it takes seven hours to pass through the whole distance and locks. The latter vary from 600 ft. × 80 ft. to 150 ft. × 30 ft., and sills 16–28 ft. deep below normal water-level of canal, the gates being moved by hydraulic machinery. The works include 160 acres of docks, with warehouses, machinery, and 95 miles of railway sidings, 6 high-level bridges, 7 swing-bridges, and the Barton swing aqueduct, 234 ft. long, for the Bridgewater Canal over the Irwell (to replace Brindley's fixed aqueduct), which latter canal had to be bought. 52,000,000 cubic yards of excavation and removal. Plant cost 980,000*l.*, and comprised engines, locomotives, steam pumps, cranes, piling machines, horses, wagons, temporary railway, etc. Principal engineer, Sir E. Leader Williams, assisted by W. Henry Hunter and others. Contractors, T. A. Walker (who died on November 25, 1889, during the progress of the work), and his executors, T. J. Reeves, L. P. Nott, and C. H. Walker, who continued. For full particulars see *History of the Manchester Ship Canal*, 2 vols., published by Sherratt & Hughes, 34 Cross Street, Manchester. Price 25*s.* Details of cost below are based on the total length of 36 miles :—

	Total.	Per Mile.
Purchase of Bridgewater Canal	1,783,000*l.*	111,438*l.*
Land and compensation	1,167,000*l.*	72,937*l.*
Constructing the canal and docks	9,000,000*l.*	562,500*l.*
Interest on capital during construction	1,050,000*l.*	65,625*l.*
Law charges, Parliamentary expenses, etc.	500,000*l.*	31,250*l.*
Whole cost	13,500,000*l.*	843,750*l.*

Average annual maintenance per mile of canal	2,000*l.*
Do. do. per acre of docks	400*l.*

Panama Canal (1904–15).—From Colon, on the Atlantic, to Panama on the Pacific. A concession was granted in 1876 to a French syndicate, which made surveys for two years and reported to an international congress at Paris in May, 1879. The Panama Canal Company was then floated, with Ferdinand de Lesseps as president, and preparatory work undertaken in 1881, the first excavation being made in January, 1882. The French scheme, however, was finally abandoned in 1904 owing to fever and bad administration, after the failure of both the first and a second company, and after only 12 miles had been cut out of the 54 originally proposed, and 50,000,000*l.* spent. On May 4, 1904, the United States Government bought the effects of the French company in Panama for 8,000,000*l.*, and started the American project as now completed. A strip of territory extending five miles on each side of the route of the canal was also purchased from Colombia for 2,000,000*l.* Colonel (now General) George W. Goethals, U.S.A. Engineers, was chairman of the Canal Commission which worked out the type and salient features.

Total length along axis, 50½ miles, but only 41½ miles within the coastlines. Rise of tide at Limon Bay in the Atlantic varies from 7 to 19 in., and from 8 to 21 ft. at Panama. The opening channel at sea-level, from Limon Bay to Gatun, is 7 miles long by 500 ft. wide and 41 ft. deep. At Gatun are three twin locks to raise vessels to the summit canal level, 85 ft. above sea, also an earthen dam, 8,000 ft. long, 1,500 to 2,000 ft. thick at the base, 100 ft. wide at top, and 115 ft. high, damming the Chagres River and forming the artificial Gatun Lake, 164 square miles area, with surface 85 ft. above sea-level, through which ships pass in a channel 500 to 1,000 ft. wide and 45 ft. deep. After 23½ miles of Gatun Lake the Gaillard Cut (formerly Culebra Cut) extends for 8 miles and 280 ft. maximum depth, with a channel 300 ft. wide and 45 ft. deep. Then a single twin lock, with 30 ft. drop, at Pedro Miguel to the small Miraflores Lake, where a channel, 1½ miles long by 500 ft. wide and 45 ft. deep, leads to Miraflores itself. Here two twin locks lower vessels, 31 ft. each lock, to the Pacific sea-level, and a channel 8 miles long, likewise 500 ft. wide and 45 ft. deep, conducts them to deep water in Panama Bay. In addition there are nearly 3 miles in locks and alongside approach walls. About 26 miles are artificial canal work, out of the total distance of 50½ miles.

Width of channel varies from 300 to 1,000 ft. at bottom, and depth 40 to 45 ft. The six pairs of locks are 1,000 ft. long × 110 ft. wide, with intermediate gates to divide them into two sections of 600 ft. and 400 ft., and 6 pairs of lock gates with steel frames and plates. There are 46 pairs of lock gates altogether, 46 to 82 ft. high, and the largest weighs 730 tons. Least depth of water over sills of locks when lake is at normal level is 41 ft.

The total excavation for the whole canal amounted to 220,000,000 cubic yards (130,000,000 in the dry, and 90,000,000 by dredges), of which about 112,000,000 yards was in the Culebra Cut, the most extensive excavation ever made. Concrete in the locks came to 4,500,000 cubic yards. Maximum number of employees at one time was 50,000 (6,000 Americans, 5,000 Europeans, and 39,000 negroes).

In addition to General Goethals, other engineers were Messrs. S. B. Williamson, chief of the Pacific Division, Gaillard, Sibert, Hodges, Goldwork, Schildhauer, Cornish, Zinn, Nichols, Alfred Noble, and others.

The canal was opened for traffic on August 15, 1914, the steamer passage being 10 hours each way. Ships are towed by electric cars or 'mules' running on rails alongside the waterway. Several landslides subsequently occurred necessitating temporary suspension of traffic till well into 1915.

Total cost was approximately as follows, the cost per mile being based on the total length of 50½ miles:—

	Total.	Per Mile.
Spent by the original French Canal Co. up to 1904 before abandonment	50,000,000*l.*	990,100*l.*
Purchase money paid to the French Canal Company	8,000,000*l.*	158,416*l.*
Sum paid to the Republic of Colombia or Panama for concession	2,000,000*l.*	39,604*l.*
Constructional cost of American scheme, including terminal facilities	65,000,000*l.*	1,287,130*l.*
Whole cost	125,000,000*l.*	2,475,250*l.*

Saulte Ste. Marie Canal (opened 1895).—In Canada, connecting Lakes Superior and Huron. Known as the 'Soo,' and passes 20,000 vessels a year round the Saulte Ste. Marie Falls. Length, 1$\frac{1}{10}$ miles. Width at bottom 142 ft., and depth 20 ft. It has the longest lock in the world, with gates operated by electric power. Total cost, 560,000*l.*, or 509,090*l.* per mile.

Suez Canal (1859–69).—Between Port Said on the Mediterranean and Suez on the Red Sea. M. Ferdinand de Lesseps, engineer and promoter. Total length all but 100 miles, including 60 miles through the shallow lakes of Menzaleh, Ballah, Timsah, and the Bitter Lakes, with and without dredging, and the rest actual canal formed by cutting. Sandy soil and a little rock. Sixty dredging machines were employed, and about 100,000,000 cubic yards of material excavated and dredged. Over 25,000 labourers were employed during the earlier period. Canal was originally 72 ft. wide at bottom, 196 to 328 ft. at water-level, and 16 ft. average depth (now increased to 147 ft., 420 ft., and 39 ft., respectively). No locks, as the canal is level throughout. Rise of tide is only about 1 ft. in the Mediterranean, and 6 ft. in the Red Sea. A slight current of 3 ft. per second keeps the canal clear. Passage takes 16 hours.

An auxiliary freshwater canal was constructed at the same time from the Nile, near Cairo, to Lake Timsah, and thence nearly parallel to the main canal as far as Suez, to supply fresh water and to convey provisions and materials, and afterwards to irrigate. It was 26 ft. wide at bottom, 56 ft. at surface, and 6½ ft. deep.

At Port Said the harbour encloses 450 acres, with an eastern breakwater 6,233 ft. long and a western breakwater 9,800 ft., composed of random concrete blocks weighing 20 tons. At Suez the outlet of the canal is protected on the south-west by a mole 2,900 ft. long, and on the north-west by a sold earthwork embankment.

Costs per mile are based on the total length of 100 miles.

	Total.	Per Mile.
Cost of promotion and preliminaries	5,300,000*l.*	53,000*l.*
Constructional works only	10,700,000*l.*	107,000*l.*
Enlargement, widening, and deepening since 1869.	4,000,000*l.*	40,000*l.*
Whole cost	20,000,000*l.*	200,000*l.*
Less indemnity granted in 1864 for loss of forced labour, about	4,000,000*l.*	40,000*l.*
Net cost	16,000,000*l.*	160,000*l.*

Welland Canal (opened 1833).—Constructed to avoid the break in communication between Lakes Erie and Ontario, Canada, caused by the falls in the Niagara River, and runs parallel to the latter on the west. Length, 26 miles. Twenty-seven locks, with total lift of 330 ft. Enlarged in 1867 to accommodate vessels of 400 tons. Again enlarged, 1874–87, to take vessels of 1,000 to 1,500 tons, so that the bottom width of canal would be 100 ft., and depth 14 ft. Locks increased to 270 ft. long by 45 ft. wide, and 14 ft. depth of water on the sills.

	Total.	Per Mile.
Cost of original canal opened in 1833	2,700,000*l.*	103,850*l.*
Cost of enlargement from 1874–87	2,300,000*l.*	88,460*l.*
Whole cost	5,000,000*l.*	192,310*l.*

(See Section XXIX, p. 1515.)

DEEP-WATER QUAYS.

The structural conditions of deep-water quays are so variable that the assumption of a unit of cost is misleading. For ocean-going shipping in the Thames, however, the rates between 1919–22 (post-war) varied from 50*l.* to 200*l.* per ft. run.

Deep-water Quay, Greenhithe (1919–21).—On the south bank of the river Thames, and was an extension of the existing wharves of the Empire Paper Mills. Tidal range over 18 ft., with 17 ft. depth at low-water ordinary spring tides. Length of new section of the approach 455 ft., with minimum width of 8 ft., and new deep-water berthage at end 303 ft. by 52 ft. width throughout, and three splays at corners. Total deck area of new works approximately 24,600 sq. ft. Quay carried out in creosoted Oregon and pitch pine, with steel superstructure. Engineers, Messrs. Carey and Latham.

Total cost, 70,783*l.*, or 2*l.* 17*s.* 7*d.* per ft. sup. of new wharf accommodation obtained. About 93*l.* per ft. run, including approaches.

Deep-water Quay, Shellhaven (1920–21).—On the Essex side of the river Thames, and consisted of the extension of a deep-water berthage for an oil storage depot. Tidal range 18 ft., with 29 ft. depth at low-water ordinary spring tides. Length of new quay approach 560 ft. by 18 ft. wide, and new deep-water berthage at end 420 ft. long by 40 ft. deck width, the two forming a T shape. Total deck area approximately 31,000 sq. ft. All of reinforced concrete on the Coignet system. Engineers, Messrs. Carey and Latham, and contractors Messrs. Mowlem & Co.

Total cost 80,000*l.*, or 2*l.* 11*s.* 7*d.* per ft. sup. of new wharf accommodation obtained. About 82*l.* per ft. run, including approaches.

DOCKS.

Cardiff, Liverpool, and London wet docks, including wharves, gates, locks, machinery, etc.: 20,000*l.* to 35,000*l.* per acre of water area.

Aberdeen, Glasgow, and Portsmouth, dry or graving docks for repairs, including equipment: 2*l.* to 4*l.* per yard cube of internal capacity.

Steel floating docks for repairs, in terms of lifting power	10*l.* to 15*l.* per ton.
Dock gates of greenheart, 70 to 90 ft. wide and 40 to 50 ft. high, including hydraulic machinery	40*s.* to 50*s.* per ft. sup.
Ditto of steel, ditto, ditto	30*s.* to 40*s.* ,,
Caissons, traversing or floating, 60 to 90 ft. wide, and 30 to 40 ft. high, including hydraulic machinery	50*s.* to 100*s.* per ft. sup. of waterway.
Dock walls, of concrete, stone, or granite, with concrete backing, including digging	25*s.* to 45*s.* per yd. cube.

Actual Costs of wet docks, including dock walls, gates, locks, machinery, etc.:—

	Per acre of Water Area. £
Avonmouth Docks, near Bristol (1868–77)	22,600
Barry Docks, near Cardiff (1889). Water area, 114 acres. Total cost, 3,072,000*l.*	26,947
Cardiff. Water area, 50 acres. Total cost, 1,500,000*l.*	30,000
,, Bute Dock Extension. Water area, 35 acres	22,000
,, West Bute Dock (1839). Water area, 22 acres. Total cost, 400,000*l.*	18,180
,, Roath Dock (1887). Water area, 33 acres. Total cost, 500,000*l.*	15,150

	Per acre of Water Area. £
Glasgow, Queen's Dock	24,500
Hull, Alexandra Dock	28,900
Immingham, near Grimsby (1912). Water area, 56 acres. Total cost, including land, railway sidings, dock sheds, coal hoists, etc., 2,600,000*l.*	46,430
Liverpool, Alexandra Dock	23,300
,, North Extension. Water area, 83 acres. Total cost, 2,640,000*l.*	31,810
London, St. Katherine's Docks	36,000
Newport, South Alexandra Docks (1893). Water area, 20 acres. Total cost, 500,000*l.*	25,000
Swansea, Prince of Wales' Docks (1879). Water area, 28 acres	18,600

Actual Costs of dry or graving docks for repairs, including equipment :—

	Per yard cube of internal capacity. £ *s.* *d.*
Aberdeen. Internal size, 524 ft. × 73 ft. at surface level. Total 46,000*l.*	1 15 0
Belfast (1905–12). Length over all, 901 ft. Total cost, 350,000*l.*	2 1 0
Glasgow. Internal capacity, 81,555 yds. cube. Stone and concrete	2 9 0
Hartlepool. Brick and concrete, 570 ft. × 75 ft. × 17 ft. deep	1 8 0
Liverpool. Gladstone Dock (1910–13). Total cost, 500,000*l.*	1 13 0
Otago, New Zealand. Internal capacity, 37,000 yds. cube. Total 75,000*l.*	2 0 0
Portsmouth. Granite with brick and concrete backing; 42 ft. deep	2 0 0

(See Section XXVIII, p. 1469.)

Drainage.

4-in. and 6-in. stoneware drains, jointed in cement, including trenches 3 ft. deep and concrete bed, 6 ins. thick	2*s.* to 3*s.* per ft. run.
Ditto ditto with manholes, ventilating pipes, etc.	5*s.* to 6*s.* per ft. run.
Manholes and inspection chambers, 3 ft. × 2 ft. 6 ins. × 3 ft. 6 ins. deep, complete, including digging, concrete, brick sides, iron cover, etc.	8*l.* to 10*l.* each.
Add extra for every additional foot in depth	16*s.* to 18*s.* per ft. deep.
Drains and sewers for estate development and town planning schemes	200*l.* to 400*l.* per acre.
Drainage and sewage disposal works for cities and towns	3*l.* to 6*l.* per inhabitant, 20*l.* to 30*l.* per house.

Reconstruction of Drainage, Stanhope Lines, Aldershot (1893).—Combined water carriage system with 4 in., 6 in., 9 in., and 12 in. glazed stoneware pipes (total, 54,670 yds. run), 2 to 6 ft. deep, 500 Jennings' latrines, 500 urinal stalls, 80 w.c.'s, with 3 gal. flushing cisterns, 200 gal. galvanised iron automatic cisterns, and 16 100-gal. brick automatic flushing tanks, with disposal of sewage by irrigation on War Department land. Occupation of barracks, 8,000 adults, 200 children, and 200 horses. Total cost, exclusive of sewage disposal works, 20,500*l.*, or 2*l.* 10*s.* per head of occupation exclusive of horses; 7*s.* 6*d.* per yd. run of excavation.

Drainage of Land.

Agricultural, or subsoil, unglazed earthenware drain pipes laid dry in 12 in. or 15 in. lengths, without jointing material and ends simply abutting. Depths and distances apart vary according to nature of soil. Cost includes digging, filling, pipes, and laying.

	Cost per acre.
In compact or heavy soils, drains 5 to 8 yds. apart, and 2 ft. 6 ins. to 3 ft. deep	6*l.* to 10*l.*
In medium soils, drains 9 to 10 yds. apart, and 3 ft. to 3 ft. 6 ins. deep	5*l.* to 6*l.*
In porous or light soils, drains 11 to 22 yds. apart, and 3 ft. 6 ins. to 4 ft. 6 ins. deep	4*l.* to 5*l.*

Dredging.

Dredging Plant.—Modern dredging appliances are of two main classes, with subdivisions and pre-war costs as follows :—

Class I.—Digging dredgers, comprising :

(*a*) Bucket dredger, or ladder (single or double), or elevator dredger, with a continuous band of buckets.

	£
With 5 ft. cube bucket, single ladder, raising 40 ft.	7,000
,, 15 ,, ,, ,, ,, 45 ,,	27,000
,, 27 ,, ,, ,, ,, 55 ,,	43,000

(*b*) Dipper dredger, with a single bucket at the extremity of a long arm or lever. Almost purely an American type.

With 1 to 2 yds. cube dipper, hull of timber, 1,600*l.* to 2,400*l.*
With 3½ to 4 yds. cube dipper, dredging to depth of 35 ft., 16,000*l.* to 18,000*l.*
With 10 yds. cube dipper, dredging to depth of 35 ft., 26,000*l.* to 28,000*l.*

(*c*) Grab or grapple dredger, with a drop bucket suspended at the end of a chain.
A twin-screw hopper dredger, with hopper capacity of 12,000 tons, fitted with five hydraulic grab cranes each of 5 tons bucket capacity, working to a depth of 47 ft., has cost 35,000*l.*

(*d*) Hand or bag and spoon dredger, which consists of a bag attached to a steel rim at the end of a long pole, and is suitable only for mud in ponds and canals.

Class II.—Suction or hydraulic dredgers, comprising:

(*a*) Sand pump dredger, with centrifugal pump.
A 2,000-ton suction hopper dredger would cost 50,000*l.*

(*b*) Suction cutter dredger, with water jets and rotary cutters.
A suction hopper dredger with hopper capacity of 70,000 cub. ft., capable of raising 4,000 tons of sand per hour from a depth of 70 ft., has cost 75,000*l.*

(*c*) Compound dredger, fitted with both the suction or suction cutter and a bucket ladder.
A sea-going hopper dredger, fitted with both ladder buckets (18 cub. ft.) and suction pumps, capable of dredging 400 to 650 yds. cube per hour from a depth of 50 ft., has cost 53,000*l.*
Rock cutters are not dredgers, but an auxiliary class.

Cost of Work.—Costs include use of plant, dredging, and removing and depositing excavated material at sea. Steam dredgers cost 10,000*l.* to 70,000*l.* each; steam hopper barges in attendance, of 800 tons or 800 yds. cube capacity, with a speed of 11 knots per hour, cost 18,000*l.* to 20,000*l.*; ordinary hopper and dredger barges, 300*l.* to 1,000*l.* Pre-war.

Description.	Material.	Per yd. cube.	Per ton.
Bucket dredging, or ladder dredging	Mud, sand, or soft clay	1*s.* to 2*s.*	9*d.* to 1*s.*
	Gravel or stiff clay	2*s.* ,, 4*s.*	1*s.* ,, 2*s.*
Grab dredging, or grapple dredging	Mud, sand, or soft clay	2*s.* ,, 4*s.*	1*s.* ,, 2*s.*
	Gravel or stiff clay	3*s.* ,, 5*s.*	2*s.* ,, 3*s.*
Hand dredging, or 'bag and spoon dredging'	Mud, sand, or soft clay	3*s.* ,, 4*s.*	2*s.* ,, 3*s.*
	Gravel or stiff clay	4*s.* ,, 6*s.*	3*s.* ,, 4*s.*
Pump dredging, 'suction or hydraulic dredging'	Mud, sand, or peat	6*d.* ,, 1*s.*	4*d.* ,, 9*d.*

Grab dredging can be done for as little as 2*d.* to 6*d.* per yd. cube, and sand pump dredging for 1*d.* ditto, but a great deal depends on the kind of spoil and distance to be carried.

Alluvial Mining.—Dredging for alluvial mining costs anything from 1*d.* to 1*s.* per yd. cube (pre-war), depending upon character of ground, depth, quantity treated, climate, transport, power, labour, management, types of dredges, capacity of buckets, operating time, etc.

Mersey.—At the bar and in the entrance channels of the Mersey nearly fifteen million cubic yards of sand were removed annually at a pre-war cost of 6*d.* per yd. cube, exclusive of interest and depreciation on the plant.

Mississippi River (1907).—Three pipe-line suction-cutter dredges got up 1,279,000 cu. yds. including cost of idle time, for 4¼*d.* per yd. cube. In 1908 the same dredges lifted 989,000 cu. yds., ditto, for 5¼*d.* per yd. cube.

Newry.—After blasting the bottom in a depth of 6 to 8 ft. at low water, the material was removed by dredging at 4*s.* to 5*s.* per yd. cube.

New York Harbour (1909).—Four sea-going suction dredgers removed 10,786,638 cu. yds., including dredging, surveys, contingencies, and supervision, for 2*d.* per yd. cube. Another dredger disposed of 1,675,562 cu. yds. at 2½*d.* per yd. cube.

Panama Canal (1910).—Costs of removal of various quantities by different kinds of dredgers worked out at:

Removal of	6,083,902 cu. yds.	by	two sea-going suction dredgers	3¾*d.* per yd. cube.
,,	1,372,665 ,, ,,		one ladder dredger	8*d.* ,,
,,	560,622 ,, ,,		,, ,,	1*s.* 1¾*d.* ,,
,,	1,013,485 ,, ,,		two small dipper dredgers	2*s.* 4*d.* ,,
,,	2,472,822 ,, ,,		two 20-in. pipe-line suction dredgers	1*s.* 2*d.* ,,
,,	5,800,000 ,, ,,		two dipper dredgers	2½*d.* to 5½*d.* ,,

Port Natal, Durban (1903–14).—Cost of pump dredging in sea, including all charges for working, maintenance, insurance, depreciation, and interest on capital, with coal at only 8*s.* per ton, 2½*d.* to 7*d.* per ton of material handled.

Severn.—Blasting and dredging the marl beds, 4*s.* per yd. cube.

Siam (1920).—Dredging heavy clay from irrigation canal in Siam, 85 ft. wide by 8 ft. deep, by a Lobnitz dipper dredge with buckets of 2½ yds. cube capacity, working at a speed of 30 to 40 seconds per dip. Total quantity raised was 312,130 cu. yds. in one place, running 9 hours per day, or an average of 26,010 cu. yds. per month. Average cost for year was 3*d.* per yd. cube, including labour, oil fuel, supplies, repairs, and every expense except interest and depreciation. Repairs, 4·3 per cent. of total cost.

Tees.—Blasting and dredging. In 1875 holes were drilled in the bed of the river Tees 7 to 9 ft. deep and 10 ft. apart, from a dredger; then dynamite blasting in 2 lb. charges. Average depth of rock blasted 4 ft. 6 in., oolite shale. 110,000 yds. cube were blasted at 3*s.* 1*d.* per yd. cube, so as to be lifted by the dredger.

Ladder dredging in the Tees, mostly in hard boulder clay, and lifting stones and tree trunks, cost 1*s.* 6¾*d.* per yd. cube.

Thames.—Contract cost of lifting ballast and clay, by ladder or bucket dredgers from the Thames below London Bridge has varied from 1*s.* 4*d.* to 2*s.* 6*d.* per yd. cube, depending on distance material had to be conveyed.

(See also p. 1496.)

ROCK-CUTTING AND DREDGING.

Rock-cutting Plant.—The sub-aqueous Lobnitz Patent Rock-breaker or Rock-cutter, made by Lobnitz & Co., Ltd., shipbuilders and engineers, Renfrew, Scotland, is usually employed. The rock-breaker chisel, or rock-cutter itself, consists of a compressed steel cone-shaped point fitted to a solid steel shaft, 15 to 18 in. diameter and 40 to 50 ft. long, depending on depth of water, and weighing from 6 to 25 tons. This drops 6 to 10 ft. on the same place, from a frame mounted on a barge fitted with steam winch, hoisting gear, steel wire ropes, mooring chains, etc. No explosives are used. The striking points are marked on a chart, and the holes are spaced about a yard apart. After a penetration of 3 ft. on one spot the rock is cut, and then dredged away in horizontal layers. The general result is 2 cu. ft. of rock broken per blow, suitable for bucket dredging afterwards to remove the pulverised stone. And 2 cu. ft.× 150 blows per hour on an average = 300 cu. ft.÷ 27 = 11 yds. cube per hour for a single-cutter machine, or say 100 yds. cube per working day of 9 hours. Output of a double-cutter machine is about one-half more. A crew of four men is required on a barge with one cutter, and six men with two cutters, the barge being shifted after a hole has been made to the next position. Skilled labour is unnecessary. 1 ton of coal is consumed per working day by a single 10-ton cutter, and 1½ tons by a double 10-ton cutter. The cost of oil, stores, and repairs does not exceed the outlay for coal and wages.

Blyth Harbour, Northumberland (1906).—Rock-cutting in friable to very hard sandstone by the Lobnitz Rock-breaker steel ram weighing 15 tons, falling 8 ft. to a depth of 3 ft. in the rock in 8 or 9 blows, to allow of being dredged to a depth of 2 ft. 6 ins. Average quantity was 908 cu. yds. of rock broken by one machine per week, night and day, allowing for all stoppages, and based on six months' working. Details per week for 908 cu. yds. was:

	£	*s.*	*d.*
Wages for men on dredger	16	1	6
Coal, stores, and water	6	10	7
Estimated cost of repairs, renewals of rams, ropes, etc.	22	0	0
Insurance at 30*s.* per cent.= 120*l.* per annum	1	19	2
908)	46	11	3
Rate per yard cube	0	1	0¼
Add 4 per cent. interest on cost of one Rock-breaker at 6,800*l.*, and 2½ per cent. for depreciation, making a further	0	0	2¼
Total cost per yard cube	0	1	2½

As compared with blasting, the rock-cutting disintegrates and breaks the rock into smaller pieces, so that the quantity lifted by the dredgers in a given time is about 15 per cent. more than that of blasted rock. The comparative cost of removal under the two systems of blasting and rock-cutting is as follows:—

	s.	d.
Blasting:—		
Drilling and blasting rock in position	3	0
Dredging and removing débris, 2*s.* 6*d.*+ 8*d.* for interest and depreciation on the dredger	3	2
Cost per yard cube	6	2
Rock-cutting:—		
Cutting rock by rock-breaker as already detailed	1	2½
Dredging and removing débris, 2*s.* 2*d.*+ 7*d.* for interest and depreciation on the dredger	2	9
Cost per yard cube	3	11½

Difference in cost per yard cube in favour of the removal of rock by means of the rock-breaker was thus 6*s.* 2*d.* *less* 3*s.* 11½*d.*= 2*s.* 2½*d.* Saving on 500,000 cu. yds. executed was accordingly 55,200*l.*, after the drilling and blasting had been tried and abandoned.

Manchester (1905–6).—Deepening a length of 14 miles of the Manchester Ship Canal from 26 ft. to 28 ft. by a Lobnitz Rock-cutter No. 1, designed to work in sandstone of varying degrees of hardness, the average quantity broken per month (over a period of 10 months) being 6,403 cu. yds. at an average cost of 9*d.* per yd. cube.

The cost of rock-breaking and dredging on the same canal in April 1907, by the Lobnitz dredger was as below. The price of one Rock-cutter was 6,800*l.*, and if 4 per cent. is allowed for interest, and 2½ per cent. for depreciation, the additional cost per yard cube is 2¼d., as added. 17,060 cu. yds. were broken, the rock being sandstone of different hardness, with some stiff marl.

	s.	d.
Breaking, excluding cost of plant, but including maintenance and repairs	0	5½
Dredging the broken rock	0	5½
Barging and tipping	0	6¾
Towage	0	2½
	1	8¼
Add interest and depreciation on cost of plant	0	2¼
Total cost per yard cube	1	10½

Suez Canal.—Deepened in 1884 by a Lobnitz dredger, with cutting rams of 3½ tons, rock removed in layers 20 in. thick, and the breaking up cost was 7*s.* 3½*d.* per yd. cube.

The canal was further deepened to 31 ft. in 1897 by a Lobnitz Rock-cutter with cutting rams of 13 tons, the average thickness of rock shattered was 31 in., and the average cost, including repairs and depreciation, was 1*s.* 4*d.* per yd. cube. Cost of raising the rock by dredgers and carrying it away in addition.

ELECTRIC POWER STATIONS.

Town.	Total Cost.	Cost of Land and Buildings.	Kilowatts Housed.	Cost of Buildings per Kilowatt.	Total Cost per Kilowatt.
	£	£	No.	£	£
Brighton	717,738	149,431	5,400	28	133
Bristol	671,616	53,550	9,050	6	74
Chichester	20,000	600 not land	200	3	100
Glasgow	1,368,134	211,172	10,993	19	124
Hackney	280,982	42,394	3,372	13	83
Metropolitan	1,802,383	435,777	18,500	24	97
Newcastle	1,192,442	169,675	20,000	8	55
Tonbridge	22,420	7,228	120	6	187
Tunbridge Wells	81,134	13,207	1,170	11	69

	£	£
Electric light installations for cities and towns, with buildings, plant, and mains complete	80 to 130	per kilowatt.
	3 ,, 5	per c.p. lamp.
Steam plant power stations	24	per kilowatt.
Oil plant power stations	23 ,, 25	,,
Capital cost of generating stations	20	,,

Power and electric stations generally, brick, exclusive of plant and machinery. 10*l.* to 25*l.* per kilowatt . . . . . 6*d.* to 8*d.* per f.c.

Aldershot electric lighting station (1902). Brick walls and slated roof . 6½*d.* ,,

Curragh electric light generating station (1913–14). For three 100-h.p. Diesel oil engines, 66 kilowatts per engine, with a 750 ampere hour battery and accessory machinery. Contains a basement for engine beds, silencer chamber, and oil-fuel store, and above, on ground level, an engine-room, battery-room, store-room, two offices, and lavatory. Brick walls in cement mortar, 1 to 3, concrete foundations, engine beds and floors, steel sashes, steel roof, boarded and covered with asbestos slates. 99,700 feet cube. Building only, exclusive of plant and machinery. Total, 2,080*l.* . . . . . 5*d.* ,,

Building, including plant and machinery. Total, 7,456*l.* . . . . 1*s.* 6*d.* ,,

Cost of foregoing per kilowatt housed, 10*l.* to 38*l.*

Extension to Curragh electric light station (1920–21). For one additional 100-h.p. Diesel oil engine and plant, 66 kw., the extension of engine-room and exhaust pit being 12 ft. long, and same width and height as existing building. Construction also similar. A corrugated iron workshop, 18 ft. × 12 ft., is attached to the end of the brick extension, and included in total cost and cubing. Lump sum tender for both together. 17,600 ft. cube total. 17*l.* external services in addition. Building only, exclusive of plant and machinery. Total, 2,188*l.* . 2*s.* 5¾*d.* ,,

Building, including plant and machinery. Total, 5,188*l.* . . . 5*s.* 10¾*d.* ,,

Cost of foregoing per kilowatt housed, 33*l.* to 79*l.*

East Ham electric power station, including tramway sheds and offices. Built by direct labour under the borough engineer. Total, 26,020*l.* . 5½*d.* ,,

Salisbury engine-room and boiler-house (1904). Brick walls and slated roof, concrete floors . . . . . 6½*d.* ,,

Usual charges for current for electric lighting . . . . . 2*d.* to 3*d.* per unit.

Ditto for heating and power purposes . . . . . 1*d.* to 2*d.* ,,

ENGINEERING FACTORIES.

Engineering factories, brick, exclusive of machinery . . . . . 4*d.* to 7*d.* per f.c.

Material	52	per cent.
Labour	37	,,
Power	5	,,
Other costs	6	,,
	100	,,

ESPLANADES.

Marine Drive, Scarborough (1905).—Road 40 ft. wide, parade 20 ft. wide, and sea-wall 20 to 40 ft. high. Of concrete, on deep filling at base of cliff. Length, 1,400 yds. Total, 102,400*l.*, or 73*l.* per yd. run.

GAS WORKS.

Gasworks.—Gasworks complete, including buildings, plant, and distributing mains:

	Small Towns.	Large Towns. or Cities.
Per head of population	30*s.* to 40*s.*	40*s.* to 50*s.*
Per ton of coal carbonised per annum	5*l.* to 6*l.*	6*l.* to 7*l.*
Per million cubic feet of gas produced per annum	500*l.* to 600*l.*	600*l.* to 700*l.*

Land.—Area of land for the erection of works at least 2 acres per million cubic feet of gas per maximum diem.

Proportionate Capital Expenditure.—Including works, distribution plant, etc.:—

On buildings and works	38	per cent.
On district mains	55	,,
On Parliamentary, promotion and engineer's expenses	7	,,
	100	

Proportionate Cost of Parts.—Including buildings and plant :—

Retort house, including benches, fireclay retorts, etc.	25 per cent.
Purification buildings, with purifiers, gas scrubbers, etc.	30 ,,
Gasholders, iron or steel, with guide framing, brick-lined tanks, concrete bottoms, and excavation	40 ,,
Station meter-house, meter, and miscellaneous	5 ,,
	100

Retort-houses.—Including foundations and brickwork to benches, etc. :—

Exclusive of plant or machinery	5*d.* to 6*d.* per f.c.
Including retorts, ironwork, and fittings	1*s.* to 2*s.* ,,

Glover-West's system for vertical gas retorts, Belfast (1913) :—
70,950*l.* for a plant to carbonise 480 tons of coal per 24 hours,
= 148*l.* ,, ,, ,, 1 ton ,, ,,

Gasholders.—Steel or iron telescopic holders, including guide framing, etc. :—

	Per 1,000 cub. ft. of capacity. £ £
Single-lift holders, up to about 50,000 cub. ft.	25 to 28
If of the spiral type, 25 per cent. less	20 ,, 22
Two-lift holders, about 250,000 cub. ft. capacity	16 ,, 20
If spirally guided, about 50 per cent. less.	8 ,, 10
Large holders, from 2 to 3 million cub. ft. capacity	9 ,, 12
The 10½-million holder at Manchester cost	5
The 12-million holder at East Greenwich Works cost	5 guineas

(See Section XXXV, p. 2309.)

GROYNES.

There are four types of groyne construction in this country—timber, concrete block, reinforced concrete, and chain cable. Cost of timber groynes for the seashore, comprising creosoted fir piles with horizontal sheeting bolted thereto, and stiffened with ties and struts. Piles well driven into sand or shingle, and executed as tide-work. Pre-war costs :

Light timber groynes, 1*l.* to 3*l.* per yard run.
Heavy ,, ,, 3*l.* ,, 6*l.* ,, ,,

The following particulars have been condensed from *Marine Works*, by E. Latham, M.I.C.E. 1922. 16*s.* Crosby Lockwood & Son, London), and the other books mentioned in each case. The first five examples are pre-war, and the last post-war.

	Cost per yd. run. £ *s.* *d.*
Bridlington.—Low timber case groynes, constructed of pitch pine piles, shod with 18-lb. pile-shoes, driven 8 ft. into the boulder clay in pairs, at 7 ft. 6 in. centres. 11 in. × 4 in. pitch pine planking inserted between the piles, so that a depth not exceeding two planks projects beyond the sand level. Timber all creosoted. Groynes spaced at a distance apart not exceeding their length, which was about 200 ft. First four groynes cost	2 14 0
Most of the others cost	1 16 9
For details see *Coast Erosion and Protection*, pp. 114–115, by E. R. Matthews, A.M.I.C.E. (1918. Charles Griffin & Co., London.)	
Eastbourne.—Timber groynes erected about 1886–96, some 70 yards apart, at right angles to the foreshore. Constructed of 9 in. × 9 in. pitch pine and oak piles, 6 to 16 ft. long, driven to an average depth of 9 ft., set 4 ft. 6 ins. apart, centre to centre, with walings 8 ins. × 6 ins. and 6 ins. × 6 ins. Planks, 9 ins. × 2 ins., are spiked to the piles in lengths of 20 ft. and over, to span four bays and break joint. Large oak land-ties fixed at right angles to the piles, and fastened to a smaller pile at back. The majority are high groynes, and were originally 8 to 10 ft. in height at shore end, and about 4 ft. at low end, and did not extend to low-water mark. The more recently constructed groynes vary from 4 ft. high at the land end to 2 ft. at low-water mark. Average length 100 yards, and cost 375*l.* each, or	3 15 0
Seven case groynes erected to the east of the pier in 1897. Pairs of 9 in. × 3 in. pitch pine piles, spaced 7 ft. 6 in. centres, with 9 in. × 3 in. planks inserted between. Average length 100 yards, and cost 68*l.* 15*s.* each, or	0 13 9
For details see *Coast Erosion and Protection*, pp. 104–106, by E. R. Matthews, A.M.I.C.E. (1918. Charles Griffin & Co., London.)	
Lowestoft (1901–1903).—North Denes. Four timber main groynes, three having a length of 290 ft., and the fourth 340 ft., spaced 1,500 ft. apart. Shoreward ends 4 ft. above high-water level, and seaward ends 3 ft. below the same level. For details see *Proceedings of the Institution of Civil Engineers*, vol. clxxxv. p 106	22 1 3

	£	s.	d.
Southwold.—Timber groynes. For details see *The Protection of Sea Shores from Erosion*, p. 23, by A. E. Carey, M.I.C.E.	4	4	0
Withernsea (1873).—Six timber groynes consisting of 13 in. piles, 22 ft. long, 5 ft. apart, driven down 12 ft., with 11 in. × 4 in. planks, 13 in. × 6½ in. struts, and foot piles. Four are 300 ft. in length, and two 350 ft. Only three planks project above sand-level. For details see *Proceedings of the Institution of Civil Enginsers*, vol. clix. p. 73	3	7	6
Blue Anchor (1921).—On the Bristol Channel, and in front of the Minehead to Watchet Road, north Somerset. Groyne 600 ft. long and two timber stockades, each 1,500 ft., parallel to existing sea-wall. Stockades consisted of 10 in. × 10 in. main piles of pitch pine, with 9 in. × 4 in. intermediate piles bolted to continuous walings. Half of total length of stockades had to be constructed by bedding the piles in mass concrete, necessitating trenching in rock. Engineer, E. Latham, M.I.C.E. Contractors, Messrs. John Cochrane & Sons, Westminster. Total about 30,000*l.* Cost per yd. run includes stockades	25	0	0

Harbours.

Artificial harbours complete, including reclamation of land, dredging, enclosure walls, breakwaters, landing stages, lighting, buoys, cranes, etc.:

5,000*l.* to 10,000*l.* per water acre enclosed.

Colombo Harbour (1874–1914).—On the west coast of Ceylon and entirely artificial. It ranks twelfth among the greatest seaports, and there is ample space for 50 steamers besides smaller craft. The enclosed area is 650 acres (over a square mile), and depth 30 to 36 ft. at low water. Rise of tide at Ceylon is only 2 ft.

South-west breakwater, 1874–85, is 4,212 ft. long, built of concrete blocks weighing 18 to 30 tons on the sloping bond system, and cost 705,200*l.*, or 167*l.* per ft. run. Extension to ditto as a further protective arm, 1907–12, is 1,800 ft. long, also of concrete blocks, and cost 380,000*l.*, or 211*l.* per ft. run. North-east breakwater, 1894–7, is 1,100 ft. long, and constructed as a rubble embankment; the north-west or island breakwater, 1900–6, is 2,657 ft. long, and made of concrete; the two together cost 500,000*l.*, or 133*l.* per ft. run. Total length of the four breakwaters about 9,770 ft., with 5 lighthouses on them, and total cost 1,585,200*l.* Graving dock, 1900–4, is 700 ft. long, 85 ft. wide, and cost 400,000*l.*; patent slip, 1900–3, is 800 ft. long, and cost 43,000*l.*; coaling depot, on 24 acres of reclaimed land, has a frontage of 2,200 ft. with 18 jetties, and cost 163,000*l.* Other services, 821,900*l.* Total expenditure from 1874 to 1914 (forty years) was 3,013,100*l.* The small Fishery Harbour immediately to the northward has a rubble arm 800 ft. long, and cost 12,000*l.* The engineers were Sir John Coode, Son, and Mathews; and the resident engineers, Sir John Kyle, M.I.C.E., Mr. J. H. Bostock, M.I.C.E., Mr. John Kyle, M.I.C.E. (son of Sir John), and Mr. A. D. Prouse, M.I.C.E.

4,636*l.* per water acre enclosed; 162*l.* per ft. run, average of breakwaters.

Dover Harbour (1898–1909).—Original Admiralty Pier, 1,000 ft. long, was built in 1847–71. Dover Harbour Board then constructed a small commercial harbour of their own in 1890, between the existing Admiralty Pier and a new east pier, of 56 acres net area, afterwards increased to 75 acres by reclaiming the foreshore. The National Harbour was proceeded with in 1898–1909, and comprised the extension of the western breakwater, or old Admiralty Pier, from 1,000 to 3,000 ft., an eastern arm, 3,320 ft., and an isolated breakwater in the middle, 4,200 ft. Total sheltering works, 9,520 ft., or nearly 2 miles long, with two entrances 740 ft. and 650 ft. wide and 42 ft. deep at low water, enclosing 610 acres, exclusive of the 75 acres in the Commercial Harbour. Height of breakwaters from bottom of foundation to parapet top 60 to 120 ft. or an average of 90 ft., with 50 ft. average depth below low-water level, and 50 ft. average thickness, built of concrete blocks, weighing 10 to 40 tons each and faced with granite above low-water level. Works include a sea-wall, 3,850 ft. long, to protect base of cliffs, a lesser sea-wall, 700 ft., and reclaiming about 20 acres of land. Engineers, Sir John Coode, Son & Mathews. Contractors, Messrs. S. Pearson & Son, Ltd. National Harbour, 610 acres, cost 4,000,000*l.*, and inside Commercial Harbour, 75 acres, 1,250,000*l.*, or a total of 685 acres and 5,250,000*l.*

National Harbour:	6,557*l.*	per water acre enclosed;	420*l.*	per ft. run of breakwater.
Commercial Harbour:	16,666*l.*	,, ,, ,,	131*l.*	,, ,, ,,
The two combined:	7,664*l.*	,, ,, ,,	551*l.*	,, ,, ,,

(See Section XXVIII, p. 1469.)

Heating.

The fewer the radiators, and the longer the run, the higher the cost per radiator. 15 ft. sup. of radiator should be supplied for every 1,000 cubic feet of space to be heated. Cost includes fittings complete, but is exclusive of boiler-house and buildings.

Heating buildings with boilers, pipes, and radiators	1*l.* to 4*l.* per 1,000 c.c.
Low-pressure hot-water heating	8*l.* ,, 10*l.* per radiator.
Hot-water work inside a building	1*s.* 6*d.* per ft. run.

(See Section XXXVI, p. 2351.)

Landing Slips.

Landing Slips, Milford Haven (1894).—Formed of Portland cement concrete, with shingle supplied by contractor, and 8 ft. wide × 3 ft. high, on 18-in. foundations. In tidework, and not exceeding 40 yards from shore. Excavation in boulders and shingle on beach. 30*s.* per foot run

Lighthouses.

Lighthouses. (All of Granite.)	Date.	Height of Focal Plane above High Water.	Engineer.	Total Cost.	Cubical Contents.	Cost per Ft. Cub. of Masonry.
		Ft.		£	f.c.	£ *s.* *d.*

Lighthouse, Northern Point, Northern Province, Ceylon (1914–16).—Tower is supported on reinforced concrete platform over hardwood piles, and built of dressed coral stone in lime mortar, cement rendered externally. Walls 2 ft. 7½ ins. thick above plinth, carried up with a uniform thickness at a batter of 1 in 48. Internal diameter of tower 8 ft. 3 ins., and height from top of foundation to reinforced concrete cap 91 ft. Fourth order light visible for 16 miles, and focal plane 97½ ft. above mean sea level. Cost, exclusive of lantern and ironwork above the cap, 1,730*l.*, or 1*s.* 6*d.* per foot cube.

Lighting.—A complete gasworks plant for a lighthouse costs about 800*l.*
Annual expenditure for gas lighting, where works are installed . . . 72*l.* per light.
" " " " where gas is supplied from elsewhere . 32*l.* "

A first-class electric lighthouse installation, including optical apparatus, lantern, dynamos, engines, air compressor, siren, etc., but not buildings, costs about 6,000*l.*

Maintenance.—Average annual cost of maintenance of an English shore lighthouse, with two keepers, is 280*l.*

Average annual cost of maintenance of an English shore lighthouse, with three keepers and a siren fog signal, is 450*l.*

Annual maintenance of a rock lighthouse, with four keepers and an explosive fog signal, is about 800*l.*; and of an electric light station, 1,100*l.*

Lightships.—Steel lightships, of average size, with power driven compressed air siren, cost about 16,000*l.*

Annual maintenance of ditto, including periodical overhaul, 1,320*l.*

Usual limits.—Length	80 to 114 ft.
Beam	20 " 24 "
Depth moulded	13 " 16 "
Tonnage	155 " 280 "

LIGHTING.

Buildings.—Cost of gas and electric lighting inside buildings, including service pipes, stop-cocks, ordinary brackets, pendants, switches, wiring, and other articles, fixed complete, but excluding meters, external gas mains, generators, etc.

	s.	*s.*	
Acetylene	20	to 40	per light.
Coal gas	30	„ 50	„
Electric	25	„ 50	„

Wiring, including all necessary wire, switches, fuses, lamps, holders, casings, etc., but not electroliers or shades, 15*s.* to 40*s.* per lamp.

Installing artificial lighting per 100 points, including oil-engine, dynamo, wires, lamps, etc., but excluding buildings:

Acetylene.	Petrol Gas.	Electric Light.
100*l.* to 200*l.*	150*l.* to 200*l.*	200*l.* to 300*l.*

Acetylene.—Cost of upkeep consists mainly in the purchase of carbide with occasional renewal of burners. A 25 c.p. burner of ordinary type consumes about 1 f.c. of gas per hour, which demands $\frac{1}{5}$ lb. carbide. With calcium carbide at 15*s.* per cwt. the cost of such a burner works out at $\frac{1}{8}$*d.* per hour. Total upkeep of a 100-light installation is between 20*l.* and 30*l.*, according to number of hours lights are used.

Gas Lighting of the Castle, Carlisle (1896).—Supply from City of Carlisle Gas Company's mains through a 600-light dry meter supplied by Company. 4 in., 3 in., and 2 in. cast-iron mains and 1½ in. to ¼ in, galvanised wrought-iron service pipes, underground pipes 3 to 3½ ft. deep. Fittings include 19 governors, 10 valves, 20 stopcocks, 10 dry meters, 572 burners, 10 Wenham lights, 12 Schulke lights, 20 Deimel lights, 18 Welsbach incandescent lights, 12 Sugg's lights, etc. Occupation of barracks, 731 adults and 72 married quarters.

Total, 1,144*l.* 36*s.* per light or point. 28*s.* per head.

Gas Lighting of Strensall Camp, near York.—Completed 1915, in extension of the York Gas Co.'s mains. Cost includes 3-in. external steel mains, 2 in. to ½ in. wrought-iron branches, brick meter-house and meters, siphons, stopcocks, burners, excavation, fixing, etc., complete, in huts and 40 married quarters for about 1,260, total of officers, N.C.O.'s, and men. 376 incandescent burners and 584 flat-flame burners, or 960 lights altogether.

Total, 1,780*l.* 37*s.* per light or point. 28*s.* per head.

Electric Lighting, Army Pay Offices, York.—Feb. 1915. 84 electric lights, mostly of 100 c.p. each, including opal glass shades, wiring, cords, switches, fuses, etc., but not cable into building or any plant, as taken from the Corporation electric main in road. 18 officers and 300 clerks.

Total, 91*l.* 22*s.* per light or point. 6*s.* per head.

Electric Lighting, Army Pay Offices Extension, York.—Aug. 1916. One-storey corrugated iron building, lined with plaster slabs. 136 electric lights, mostly of 100 c.p. and 50 c.p. metal filament lamps, including pendants, opal and holophane glass shades, wiring, cords, 109 switches, fuses, distribution boards, etc. Direct-current supply on the three-wire system taken from the Corporation electric main in adjacent road. 24 officers and 400 clerks.

Total, 137*l.* 20*s.* per light or point. 6*s.* 6*d.* per head.

Railway Coaches.—	£
Cost of fitting a railway coach with electric light	130
„ „ „ „ incandescent gas	34
Annual maintenance of an electric lit railway coach	13
„ „ a gas „ „	7

STREET LIGHTING AT CROYDON.

(1910.)

Type of Lamp.	Number of Lamps.	Distance Apart.	Total Cost.	Average c.p. per Mile.	Cost per c.p. per Annum.
	No.	Yds.	£	c.p.	*d.*
Incandescent gas	2,137	80	7,062	839	15·86
Incandescent electric	90	66	288	1,373	13·71
Electric arcs	428	65	7,212	10,537	11·32

Locks.

Including foundations, invert, walls, gates, sills, machinery, lock-keeper's cottage, etc.

Brick and concrete	Per yd. cu. of internal capacity 30*s.* to 50*s.*
Stone and concrete	,, ,, ,, 40*s.* ,, 60*s.*
Canal locks	each 5,000*l.* to 15,000*l.*
River locks	,, 15,000*l.* ,, 30,000*l.*

Marine Piers.

Timber and iron piers for seaside places, with creosoted fir or iron screw piles, averaging 40 ft. long and driven up to 15 ft. in sand or shingle, including braces, ties, timber decking, railings, tarring, gates, seats, etc.

Gangway or promenade portion	8*s.* to 12*s.* per ft. sup.
Landing stage or head to pier	10*s.* ,, 16*s.* ,,

Military Pier, Tilbury (1896).—450 ft. long by 16 ft. wide, or 7,200 ft. sup. Height above h.w.o.s.t. level, 4 ft., and above l.w.o.s.t. level, 20 ft. Foundation, 3 ft. of mud over 20 ft. of chalk, the distance bored. Substructure of wrought-iron piles, 10 ft. apart, with rod iron braces, on which are fixed wrought-iron girders with intermediate joists supporting timber decking. 18-in. gauge tramway rails, 24 lbs. per yard, and steam crane to lift 10 tons. Total cost, including 500*l.* for hoisting machinery, 3,200*l.*, or 8*s.* 11*d.* per ft. sup.

Batticaloa Jetty, Eastern Province, Ceylon (1900).—Timber pier, 50 ft. long, with return portion 22 ft. long, and 10 ft. wide. Cost, 5*s.* 6*d.* per ft. sup.

Galle Jetty, Southern Province, Ceylon (1916).—Jetty is 162 ft. long × 20 ft. wide, carried on concrete cylinders 6 ft. diameter, spaced 20 ft. centre to centre longitudinally and 14 ft. transversely, end pair being taken down to a depth of 20 ft. Special cylinders, 8 ft. diameter, form seats for two 3-ton cranes. Jetty is roofed for a length of 137 ft. Cost, 4,923*l.*, or 1*l.* 10*s.* per ft. sup. Cost of cylinders sunk, 6 ft. diameter, 3*l.* 19*s.*, and 8 ft. diameter, 5*l.* 3*s.*, per ft. run.

Kalkudah Jetty, Eastern Province, Ceylon (1901).—Jetty of iron, with wooden joists and planking, 165 ft. long × 28 ft. wide, and landings. Piles of H-iron section, 9 ins. × 7 ins., carried through a stratum of sand about 8 ft. into the coral bed of 1 to 2 ft. thick. Cross bracing, walings, fenders, etc. Corrugated iron roof over 122 ft. of length, supported on iron principals carried by H-iron standards, 8 ins. × 6 ins. Water 8 ft. deep at end of pier. Cost, including crane seat, 2,516*l.*, or 11*s.* per ft. sup. of platform area.

Paddiruppu Jetty, Eastern Province, Ceylon (1900).—70 ft. long with a tee head 30 ft. × 6 ft. wide, constructed of Palu timber with brick abutment. Cost, 8*s.* per ft. sup.

Mining.

(See Section XXXVII, p.. 2405.)

Pile Driving.

(See p. 588.)

Railways.

Average cost of railways, main lines, 4 ft. 8½ in. gauge, double track, total capital expenditure, including land and all charges :—

	£	£	
In England	35,000 to	45,000	per mile.
,, Scotland	25,000 ,,	35,000	,,
,, Ireland (5 ft. 3 in. gauge)	20,000 ,,	25,000	,,
,, Europe	15,000 ,,	25,000	,,
,, India (5 ft. 6 in. and metre gauge)	12,000 ,,	25,000	,,

Legal expenses	5 ,,
	100

	£	£	
Main lines, construction work and stations only	10,000 to	20,000	per mile.
Light railways ,, ,, ,, ,,	1,000 ,,	3,000	,,
Permanent way, single line, light construction, 4 ft. 8½ in. gauge, in flat country, cuttings and banks averaging 3 ft., rails 55 lbs. per yard, ballast 15 ins. deep, including stations and permanent works, but excluding land and rolling stock	5,000 ,,	6,000	,,
Ditto, heavy construction, 75-lb. rails, and 24 ins. ballast	6,000 ,,	8,000	,,
Yearly maintenance of permanent way	200 ,,	250	,,
Rolling stock, single line, depends on kind of traffic	700 ,,	1,000	,,
Permanent way, double line, in excess of above figures	50 ,,	75	per cent.
Rolling stock ,, ,, ,, ,, ,,	10 ,,	30	,,

Working expenses in England average 50 per cent. of the gross receipts.
,, ,, Scotland ,, 45 ,, ,, ,,
,, ,, Ireland ,, 40 ,, ,, ,,
Average gross receipts, 4*s.* to 6*s.* per train mile.

Railway Footbridges.—Of iron or steel, including foundations, supports, girders, floor, staircases, lattice sides, etc., erected complete, 5 ft. wide.
250*l.* to 350*l.* each, 30 to 40 ft. span, or 15*s.* to 20*s.* per ft. sup.

Railway Viaducts.—On the Great Western Railway there are a great many viaducts, especially in Cornwall, commencing at 50 to 60 ft. deep, and being as much as 90 or 100 ft., and even up to 150 ft., in the centre of the gorge. They are, as a rule, about 60 ft. spans between the piers, which is found to be the economical width. Segmental arches nearly, but not quite, semi-circular, 3 ft. thick at centre, and 3 ft. 9 ins. at the springing. Piers, 7 ft. 6 ins. wide at the top, tapering on every side at 1 in 32. This gives a pressure of about 8 tons per square foot on the masonry. The cost comes out for such a structure, carrying two lines of way, at 1*l.* per yard forward per foot high, measured from ground to rail. That is, for example, a viaduct 200 yards long, and averaging 70 ft. in depth, will cost 14,000*l.*

Avon Viaduct.—On the Midland Railway, and of brick. 720 ft. long, 51 ft. high, and 11 arches of 50 ft. span. Cost, 14,000*l.*, or 19*l.* per ft. run.

Congleton Viaduct.—On the Manchester and Birmingham Railway, and of stone. 3,080 ft. long, or over ½ mile, and 106 ft. high. Cost, 113,000*l.*, or 37*l.* per ft. run.

Dove Viaduct.—On the same line, and of brick. 1,716 ft. long, 88 ft. high, and 23 arches of 63 ft. span. Cost, 54,000*l.*, or 32*l.* per ft. run.

Viaduct over the River Eye, Berwickshire (1889).—Six openings of 50 ft. clear span, 55 ft. 3 ins. between centres of piers, and extreme height above bed of stream 60 ft. Total length of bridge 331 ft. and 15 ft. wide; single track. Abutments of 1 to 7 concrete. Five piers, 45 ft. high and 12 ft. wide at top, with 9-in. and 18-in. brick face and concrete hearting, and 9-in. brick wall up the centre. Superstructure of lattice main girders 8 ft. apart, with cross girders of 10-in. × 5-in. rolled iron joists, 40 lbs. per ft. run. Flooring of 4-in. planking, and the rails carried by longitudinal beams, 14 ins. × 12 ins. Cost, 3,700*l.*, or 11*l.* per ft. run, or 15*s.* per ft. sup.

Viaduct on the Gifford Light Railway, Haddingtonshire (1900).—Four spans of 42 ft. 8 ins., centre to centre of three piers, with 1 to 6 concrete foundations. Height to rail level above the bed of stream is 50 ft., and length over all 194 ft. by 18 ft. wide; single track. Masonry piers, haunches, and abutments, and brick arches over openings. Cost, 2,043*l.*, or 11*l.* per ft. run, or 12*s.* per ft. sup.

New York Elevated Railroad (1872–80).—Steam traction. Two lines of way supported on square wrought-iron lattice-work columns, let into cast-iron base blocks founded on brickwork and concrete, at distances of 37 to 44 ft. apart. Rails of Vignoles or flange pattern, of Bessemer steel, weighing 50 lbs. per yd. run, spiked to cross timber sleepers and guarded by longitudinal timbers. Sharpest curve is 90-ft. radius. Steepest gradient, 1 in 50 for a length of 800 yds. Stations about ⅛ mile apart, with platforms 200 ft. long and 13 ft. wide. No payment was made for way-leave along the streets, nor for compensation to frontages. Length, 35 miles. Total cost, 2,870,000*l.* Cost per mile of double track :—

	£
Foundations, columns, girders, superstructure, and permanent way	57,696
Railway stations and platforms	12,000
Rolling stock, 5 locomotives and 12 cars	11,680
Per mile of double track	81,376

Tube or Underground Railways.—Electric traction, as constructed in London. Two tracks 4 ft. 8½ in. gauge, each laid in a separate tunnel, 11 to 12 ft. diameter. 300,000*l.* to 600,000*l.* per mile of double track.

	£
London (Central), 1891–1900, 6 miles, 13 stations	580,000 per mile of double track.
London (Waterloo and City), opened 1898, 1½ miles	340,000 „ „ „

Steam Traction.—Two tracks, 4 ft. 8½ in. gauge, laid in elliptical tunnel, 29 ft. wide and 17 ft. high, of 27 in. brickwork on concrete foundations.

	£
London (Metropolitan), 1863–84	600,000 per mile of double track.
London (Metropolitan District), 1864-84	250,000 „ „ „

Both the foregoing have since been converted to electric traction, completed in 1905. The Metropolitan has 32 electric miles, and the "District" 28 electric miles.

Cost of electrification only, exclusive of power stations, sub-stations, rolling stock, etc., 5,000*l.* to 10,000*l.* per mile of double track.

Cost of Indian Railways.—For the year 1895 the capital cost (rupee at 1*s.* 3¼*d.*) of Indian railways was :—

	£
Standard gauge, 5 ft. 6 ins.	10,095 average cost per mile.
Metre gauge, 3 ft. 3⅜ ins.	4,519 „ „
Special gauges, 2 ft. 6 ins. and 2 ft.	2,093 „ „

London Railway Stations.

Particulars.	Cannon Street, London, South-Eastern Railway.		Charing Cross, London, South-Eastern Railway.	
	Total.	Per F.S.	Total.	Per F.S.
		£ *s.* *d.*		£ *s.* *d.*
Area, exclusive of forecourt	F.S. 152,632	—	F.S. 103,672	—
Cost of substructure	£ 74,962	0 9 10	£ 41,422	0 8 0
Cost of superstructure	£157,262	1 0 7	£111,604	1 1 6

Cost of land	£572,370	3 15 7	£302,808	2 18 5

Charing Cross Station roof has since been rebuilt with a different type (1906).

Light Railways.

Narrow-gauge Railways.—Approximate cost, including works and rolling stock, cuttings and embankments 2 ft. deep, and ballast 6 ins. to 14 ins. deep.

Gauge.	Weight of Engines exclusive of Tender.	Max. Load per Wheel.	Weight per Yard of each Rail.	Cost per Mile.
Ft. Ins.	Tons.	Tons.	Lbs.	£ £
2 0	6	1	20	1,500 to 2,000
2 6	9	1½	25	2,500 „ 3,000
3 0	12	2	30	3,000 „ 3,500
3 3½	17	3	40	3,500 „ 4,500
3 6	20	3½	50	4,000 „ 5,000

Belgium.—Over 1,000 miles of minor lines have been constructed at a cost, including rolling stock and all outlay, of rather less than 3,000*l.* a mile. These are generally on the metre gauge (3 ft. 3⅜ ins.), and as many of them appear to be laid on the roads the cost of land is very small. They earn about 6*l.* per mile per week, and working expenses are 66 per cent., or 4*l.* per mile per week. . Net earnings of 2*l.* per mile per week give a return for over 3 per cent. per annum on the capital.

England.—In England a line on the standard gauge, with no heavy work, would cost twice as much as the Belgian metre gauge railways, or say 6,000*l.* per mile. As regards land, a light railway can seldom do with less than an average width of 1 chain (66 ft.) or 8 acres per mile, and this at 100*l.* per acre comes to 800*l.* per mile. Hence to run the line on a strip of green alongside a road would save a good deal of expense, but this might involve bad gradients and sharp curves and the maximum speed would be reduced. The following are some actual costs :—

Clogher Valley Railway, Ireland (1885–87).—Length 37 miles, 3 ft. gauge, 45-lb. rail, and runs for the most part on the side of the road. Cost, 3,300*l.* per mile. It earns about 4*l.* per mile per week, but this is mostly absorbed in working expenses.

Listowel and Ballybunion Railway, Ireland (1888).—Length 9 miles, mono-rail supported on steel trestles, fastened to steel sleepers resting on wooden sleepers, with gradients up to 1 in 45 and worked by locomotives. Cost, including rolling stock, 3,666*l.* per mile.

Wisbech and Upwell Light Railway, Cambridgeshire.—Length 5¾ miles, with 2 miles of sidings, standard gauge, 50-lb. rail, and runs mostly on the edge of the road. Cost, excluding sidings, 7,000*l.* per mile of line. The earnings are about 9*l.*, and the expenses 7*l.* per mile per week.

Agrails.—The Decauville tracks of the new light railways, or ' agrails ' as they are called, did admirable service at the front, both in France and Belgium. They can be laid at a cost of 2,500*l.* per mile, and are now being put forward as a rival or as an adjunct to motor lorry traffic, to save the costly wear and tear of roads and to relieve congestion. They can be run on the edge of existing roads, with sidings on the various farms, but are only suitable for comparatively flat districts. The old narrow-gauge railways were too solidly and expensively built, but the agrails are of very light construction and should prove most useful.

River Canalisation, see Section XXIX, p. 1515.)

River Regulation, see Section XXIX, p. 1515.)

Roads.

Main roads, 30 to 40 ft. wide, for heavy traffic, constructed complete, including bottoming, metalling, gravelling, watering, and steam rolling	£	£	3,000 to 5,000 per mile
By-roads, 20 to 30 ft. wide, for light traffic, and ditto	ditto	ditto	1,000 „ 3,000 „

Tarred macadam ,,	0 4 ,, 0	9	,, ,,

Cost per Head.—Cost per head of population for maintenance, repair, and improvements to roads, 6*s.* to 7*s.* per annum.

Damages.—Cost of maintenance has increased about 30 per cent. within recent years owing to traction engine and motor traffic. Damage through traction engines, steam lorries or carts is often assessed at 1*d.* to 2*d.* per ton per mile conveyed over the road. Damage by 'extraordinary traffic' sometimes 2*l.* to 3*l.* per mile.

Supervision.—Cost of supervision, including county surveyor's and clerk's salaries, office expenses, audit of urban accounts, etc., 3 to 6 per cent. on cost of maintenance.

(See also 'Roads,' Section XV, p. 787.)

ROOFS.

	£ £

Victoria Station and Charing Cross Station have since been entirely rebuilt.

SEA-WALLS.

Sea-walls to protect coast line, formed of 1 to 6 Portland cement concrete, 10 ft. high from base to top, 4 ft. average thickness, including foundations and excavating in clay, in tide-work, pre-war average cost—

6*l.* per yd. run, or 2*l.* per ft. run.

Pre-war actual costs from *Marine Works*, by E. Latham, M.I.C.E. (1922. 16*s.* Crosby Lockwood & Son, London.)

	Cost per yd. run. £ s. d.
Bridlington.—Alexandra sea-walls (1879). 340 yards long, of mass concrete 5 ft. thick at base and 3 ft. at top, curved on face. Concrete apron, 9 ft. wide, and 2 to 2½ ft. thick, the toe-piece being 6 ft. deep and 18 ins. thick. Back of wall is battered 1½ in. per foot. Counterforts at 20 ft. centres. Wall is 20 ft. high, with projecting cornice, coping, and handrail. Chains embedded to act as bonds for the concrete. For details see *Coast Erosion and Protection*, pp. 49–50, by E. R. Matthews, A.M.I.C.E. (1918. Charles Griffin & Co., London); and *Proceedings of the Institution of Civil Engineers*, vol. clix. p. 65. Total, £5,657	16 12 9

	Cost per yd. run. £ s. d.
Bridlington.—Beconsfield sea-wall (1888). 340 yards long, with Bramley Fall rock-faced stone and concrete backing. 1¾ in. wrought-iron tie-rods at intervals. 12 ft. 3 ins. thick at base, and 4 ft. at top, stepped and curved on face. Total height, 25 ft. 7 ins., with projectng cornice, coping, and handrail. Counterforts, 3 ft. 6 ins. by 3 ft. 6 ins, and 20 ft. apart, centre to centre. For details see *Coast Erosion and Protection*, pp. 47-48, by E. R. Matthews, AM.I.C.E. (1918. Charles Griffin & Co., London.) Total, £10,000	29 8 3
Bridlington.—Sewerby sea-defence (1896). 305 yards long. Combination of rubble and timber, with two rows of 12 in. × 12 in. pitch-pine piles, 10 ft. apart. Front piles are 15 ft. long driven 9 ft. into the clay, and back piles 23 ft., driven 10 ft., with tie piece, 9 ins. × 4 ins. Face of 11 in. × 3 in. planking, and back planking 11 ins. ×4 ins., with 9 in. ×6 in. bearers and 11 in. ×4 in. ribs. Puddle clay backing, 2 ft. 6 ins. thick. Block chalk filling between the timber work. Foot-path on top. For details see *Coast Erosion and Protection*, pp. 86–88, by E. R. Matthews, A.M.I.C.E. (1918. Charles Griffin & Co., London); and *Proceedings of the Institution of Civil Engineers*, vol. clix. p. 65. Total, £3,000	9 16 8
Extension of ditto in 1899, by 82 yards, £788	9 12 2
Chatham (1913).—Reinforced concrete revetment on the De Muralt system on the banks of the Medway. Protects a length of 90 yds. of bank between two wharves	7 15 5
Frinton (1912–13).—Reinforced concrete apron 200 yds. long, to protect a stone pitched sea-wall at Frinton in Essex, which was being undermined by the waves. Apron 12 ft. wide, sloping 1 in 12, and 4 ins. thick, reinforced with Clinton fabric and ½ in. steel bars. Front toe wall, 9 ins. thick and 2 ft. high, with ½ in. steel bar reinforcement. 6 in. × 3 in. reinforced concrete ribs, with ½ in. steel bars	2 5 0
Hornsea.—Reinforced concrete sea-wall. For details see *Proceedings of the Institution of Civil Engineers*, vol. cxxxv. p. 151	39 0 0
Lowestoft (1901–1903).—North Denes. Mass concrete sea-wall on steel piles, including steps, filling, and excavation. Total length with returns, 5,744 ft. run. Cost per yd. cube, 21*s.* 2*d.* For details see *Proceedings of the Institution of Civil Engineers*, vol. clxxxv. p. 106	5 11 6
Maintenance.—Maintenance of earthen embankments along river fronts or sea shores, about 18 ft. high to top of wall and protected by stone pitching or light reinforced concrete revetment; average cost of maintenance per annum (1910–13) when in normal repair	4*d.* to 4½*d.*

Sewage Works

Sewage disposal works for cities and towns	3*l.* to 6*l.* per inhabitant.
Bacteria filter-beds with earth embankments and floors, completed with clay puddle, and filled in with clinker or coke breeze 3 ft. deep	5*s.* to 10*s.* per yd. sup.
Ditto with concrete walls, and clinker or coke breeze 4 ft. deep	20*s.* to 30*s.* ,,

Precipitation and sludge tanks in the north-west of England, to treat a million gallons of sewage daily, built in 1910. From actual tenders received.

	£
Scheme with cast-iron tank plates	7,000
,, ,, brickwork in cement	6,000
,, ,, reinforced concrete	4,500

Bio-aëration System.—Complete works on the bio-aëration system, including aëration or circulating tanks, settling tanks of the Dortmund type, gauging chambers, sludge wells, motor houses, pump houses, etc., cost from 25,000*l.* to 30,000*l.* per million gallons, d.w.f., according to size and local circumstances (1924).

Activated Sludge Process.—The estimated cost for a complete activated sludge scheme, dealing with all storm water and treating all the sludge, is 1*l.* per head (1924).

Reading.—Activated sludge plant on the diffused air method, completed in 1924, designed to treat the whole flow of the city, amounting to 3½ million gallons d.w.f. per 24 hours, from an estimated future population of 120,000, cost 72,813*l.*, or 12*s.* 1½*d.* per head.

Strensall Camp Sewage Works, near York (1914–16).—For 1,000 nominal number of troops at 20 gals. per head per day, or 20,000 gals. sewage per day. Lift system, ground being low and sandy. Drainage connections comprised replacing 86 e.c.'s by w.c.'s, 18 additional w.c.'s, or 104 total w.c.'s, 234 gullies, and 80 manholes, with 4-in. and 6-in. stoneware drains gravitating to the ejectors. Brick engine shed, 15 ft. by 14 ft., for air compressor plant with 2 gas engines, and 4 ejector pits, with 12-in. concrete walls lined with ⅝-in. cast-iron plates, and concrete floors with

expanded metal; pits octagonal in plan, 12 ft. internal diameter and 12 ft. average depth, containing 5 pneumatic ejectors, 25 gallons each, 1 pit holding 2 ejectors. 2½ in. steel compressed air mains from engine-house to ejectors, which raise sewage to the 5-in. and 6-in. cast-iron rising main drains and thence 1,700 yards (about a mile) to the outfall works. Total lift for sewage, 19 feet. Outfall works include two reinforced 6-in. concrete tanks, 20 ft. × 10 ft. × 6 ft. each, containing 7,500 gallons, or 15,000 gallons altogether; two brick sludge beds, 20 ft. × 10 ft. × 3 ft. each, with 10-in. screened ashes at bottom and 4-in. agricultural drains on 6-in. concrete floor; two circular filter beds, 46 ft. diameter, with rubble sides and reinforced concrete floors filled with 5-ft. furnace clinker, ½-in. to 4-in. gauge, the liquid sewage being distributed by a revolving sprinkler delivering 84,000 gallons per day. Special filter tiles on floor for aeration, concrete surface channel all round, and effluent then taken by waterways for land irrigation prior to discharging into existing ditch. Cost under five separate contracts:—

	£
Drainage connections, w.c.'s, stoneware drains, and manholes	2,710
Brick engine shed, and four concrete and iron ejector pits	775
Five ejectors, compressors, two gas engines, 2½-in. steel air mains, and 5-in. and 6-in. cast-iron main drains	1,837
Outfall works, including tool house, wire fence, and entrance road	2,035
Preparation of 13 acres of land, waterways and ditches for effluent	493
Total cost	7,850

Cost per head, 7*l.* 17*s.*, or 392*l.* 10*s.* per 1,000 gals. per day treated.

STANDS.

Permanent stands for athletic or race meetings, displays, processions, reviews, etc., constructed of brick, concrete, or reinforced concrete, with refreshment rooms, kitchens, offices, weighing and saddling rooms, lavatories, drainage, water supply, electric light, seats, etc., roofed or partly roofed—

2*l.* to 3*l.* per spectator, or head of accommodation.

Imperial Stadium, Wembley, near London (1920–1923).—Major axis, overall length, 900 ft., and maximum overall width 650 ft. Oblong of grass for football and sports in centre, 492 ft. × 260 ft., with cinder running tracks, encircled by a wide stepped slope for spectators, beyond which begins the structural work with terraces of concrete steps, roofed in for 650 ft. on each side of the stadium and provided with seats. Total accommodation, including seated grand stands, ring seats, standing enclosures and terraces, 125,200 spectators. A space of 16 ins. is allotted per ring seat, and 17½ ins. for a grand stand seat. Royal box, banqueting hall, 215 ft. × 70 ft., for 1,000 people, dressing-rooms, shower baths, lavatories, board-room, box office, gymnasium with seats for 250 spectators, recreation room with billiard tables and reading tables, buffets, cloak-rooms, tea-rooms for 600 people at a time, observation gallery, offices, press gallery, special heating, 96 turnstiles, telephones, electric lighting and cooking, wireless, good water supply and drainage, etc. The whole structure is of reinforced concrete on a steel skeleton, and there are 25,000 tons of concrete, 1,400 tons of structural steelwork, 31 terraces of concrete steps on steel joists, girders, and stanchions, and steel-framed roofs covered with corrugated asbestos sheets. Height from ground to roof eaves of stand is 50 ft. Two towers 160 ft. high, flank the royal entrance, and high walls on main frontage, with arched openings with an average span of 50 ft. The whole structure is larger than the Coliseum, Rome, which held 80,000 people. Architects, Sir John W. Simpson, F.R.I.B.A., and Mr. Maxwell Ayrton, F.R.I.B.A. Engineer, Sir Evan O. Williams, B.Sc., A.M.I.C.E. General contractors, Sir Robert McAlpine & Sons, and numerous sub-contractors. Total cost, 300,000*l.*, or 2*l.* 8*s.* per spectator.

STEAM EXCAVATING.

The 'Ruston Crane Navvy' is made in five standard sizes with bucket capacities varying from ⅝ to 4 cubic yards capacity and weighing from 16 to 120 tons net, and will do the work of from 30 to 200 men. The cost may be reckoned from 2*d.* to 6*d.* per yard cube; the harder the material the greater the saving. A medium size machine fitted with a 2¾ cubic yard bucket will readily excavate and load into wagons 800 to 1,000 tons of ironstone or stiff clay per day of 8 hours at a pre-war cost of 2*d.* per cubic yard, or 3*d.* including interest, depreciation, and repairs. The following can be reckoned upon as a fair average output under ordinarily good working conditions in a day of 8 hours:

Machine with	⅝	cubic yard bucket	200 in medium clay	to 450 in sand.
,,	1½	,, ,,	300 ,, boulder clay	,, 800 ,,
,,	2	,, ,,	400 ,, well-blasted rock	,, 1,000 ,,
,,	2¾	,, ,,	500 ,, ,,	,, 1,500 ,,
,,	4	,, ,,	800 ,, ,,	,, 2,500 ,,

A 'Wilson' excavator will dig 400 to 630 yards cube per working day, at a rate of 1*d.* to 6*d.* per yard delivered into wagons, a gang of 14 men being required.

A 'Whitaker' machine will do as much as 720 yards cube per day, but the average is 500 yards at a price of ¾*d.* per yard. The buckets are 1½ yard cube capacity, the crane 10 tons, and the total weight of the machine 32 tons.

French and German endless bucket excavators are particularly useful for digging in light soil or stiff clay, and to a depth of 16 or 20 ft. at a time. The average day's work is 1,200 to 1,500 yards cube at a cost of 5*d.* per yard. They need 35 men in attendance.

Stationary or travelling steam cranes may be employed to work iron or wooden skips, which are like large buckets or boxes respectively, and hold ½, ¾, or 1 yard cube, made to discharge from the crane over a wagon. Woodford's patent steel skips are best, self-righting, and with safety catch.

In working grabs, the cost in some cases may be taken as about half the price of hand labour, the saving is greater when under water. When dredging Limerick harbour with a Priestman's grab the average cost of dredging and discharging was 1¾*d.* per ton.

TANKS.

Tanks, cast-iron, 5,000 to 10,000 gals., supplied only.	1*s.* 6*d.* to 2*s.* per f.c., 3*d.* to 4*d.* per gal.
„ wrot.-iron „ „ „ „	2*s.* to 2*s.* 6*d.* „ 4*d.* „ 5*d.* „
Galvanised wrot.-iron square cisterns, 14 W.G., 50 to 500 gals. capacity, exclusive of fixing	2*s.* 6*d.* to 4*s.* „ 5*d.* „ 8*d.* „
Add if covered in at top	6*d.* to 1*s.* „ 1*d.* „ 2*d.* „

TELEPHONES.

Providing and fixing complete, including copper line weighing 150 lbs. per mile, with poles, brackets, insulators, etc.

25*l.* for ¼ mile ; 30*l.* for ½ mile ; 38*l.* for 1 mile ; and beyond, 30*l.* per mile.

TRAMWAYS.

Approximate Cost per Mile.	Single Track. £ £	Double Track. £ £
Electric tramways, overhead trolley system, with span wires, including buildings and equipment, but exclusive of generating station for electricity	9,000 to 12,000	15,000 to 20,000
Ditto, ditto, with side brackets or centre poles	7,000 „ 10,000	14,000 „ 18,000
Overhead equipment, including supports :—		
Span wire construction	1,200 „ 1,500	1,600 „ 2,000
Bracket arm construction	900 „ 1,200	1,300 „ 1,700
Permanent way, granite setts :—		
3 ft. 6 in. gauge, 100 lb. rails	4,000 „ 5,000	8,000 „ 9,000
4 ft. 8½ in. gauge, 100 lb. rails	5,000 „ 6,000	9,000 „ 10,000
Conduit system, centre slot, with underground wires, including special work	12,000 „ 15,000	23,000 „ 28,000
Cable tramways, mechanical, with underground cables, etc.	15,000 „ 20,000	25,000 „ 30,000
Horse tramways, with stables, cars, etc.	6,000 „ 9,000	12,000 „ 15,000
Steam tramways, with locomotives and cars	7,000 „ 10,000	13,000 „ 16,000

The cost of line per mile varies according to power station, plant, number of cars, cables, class of paving for permanent way, gauge and weight of tram-rails, etc.

PROPORTIONATE COST OF PARTS.

	Per cent.
Permanent-way construction	50
Overhead construction	10
Street alterations, etc.	5
Cables, feeder pillars, etc.	10

Dover, overhead trolley system, 3 ft. 6 in. gauge, exclusive of power station, total 28,000*l.*, per mile of single track	7,000
Manchester (1905), overhead trolley system, current provided by the lighting station, cost per mile of track	12,500
Permanent way, cables, and electrical equipment only, per mile of track	6,575
Portsmouth, overhead trolley system, 4 ft. 7¾ in. 'Scotch' gauge, exclusive of power station, but including taking up old tram lines and concrete foundations and new ditto, cost per mile of double track	21,000
Ditto, including power station and machinery, ditto	23,900
Staffordshire, Bristol, and Coventry, capital expenditure on electric tramways per mile of single track, average	12,000
Wolverhampton, permanent way, electrical equipment, and cables, on the Lorain surface contact system, per mile	8,600

WORKING EXPENSES.

	Per car mile. *d.*
Aberdeen, electric overhead trolley system, including interest on sinking fund	9·00
Birmingham, 1890–1, electric accumulator	9·90
,, ,, cable traction	6·33
,, ,, horse traction	9·79
,, ,, steam traction	10·99
Dover, overhead trolley system, including interest on sinking fund	8·75
London County Council conduit tramways worked on purchased current, in 1905–6	8·02
Staffordshire, Bristol, and Coventry electric trams	6·30
Modern electric trolley lines generating their own current work	5*d.* to 6*d.*
,, ,, ,, where current is purchased	6*d.* to 7½*d.*

The Peak Cable Tramway, Hong-Kong (1888).—Rises 1,207 ft. in a total length of 4,690 ft. Maximum gradient 1 in 2, and minimum 1 in 25. Three intermediate stations, and top and bottom termini. Single track 5 ft. gauge of two 30 lb. rails, and steel sleepers 24 lbs. per yard. Midway crossing place 130 ft. in the clear, above which the track is formed of three rails. Power-house at summit, with two engines, boilers, etc. Steel haulage cable, 3½ in. circumference, weighing 2 lbs. per ft. run. Rolling stock consists of two cars, each holding 45 passengers, and one ascends while the other descends, 9 minutes per trip. Total cost, 20,000*l.*, or at the rate of 22,516*l.* per mile.

(See p 761.)

Tube Wells.

Driven tube wells sunk in ordinary ground, including use of tackle, well driver's time, and wrought-iron lap-welded tubes, approximate costs as detailed below; add pumps. The quantity of water obtainable depends on the water-bearing strata, and can be increased by connecting two or more wells together. See also 'Artesian Wells.'

Depth of Tubes, etc.

		Internal Diameter.		
		1¼ in.	2 in.	3 in.
Not exceeding 15 ft. deep	each	4*l.*	7*l.*	11*l.*

Special point of tough yellow metal for waters impregnated with iron	,,	2*l.*	3*l.*	5*l.*
Average quantity of water obtained, gallons per hour:		150 to 900;	300 to 1,500;	450 to 3,000.

Description of Pump.

	Size of barrel.		
	3 in.	3½ in.	4 in.
Standard pump, with valve door, supplied only, each	3*l.*	4*l.*	5*l.*

Tunnels.

Chab Tunnel (1897-8).—On the Mari-Attock Railway, Punjab, India. Constructed between June, 1897, and July, 1898, through sandstone. Length, 1,312 ft., or about ¼ mile, of which 312 ft. were cut and cover. Average progress per day, 1½ yds. Total cost, 18,690*l.* (equivalent to 74,760*l.* per mile), or 43*l.* per yard run. Maximum altitude above sea-level 1,350 ft., and greatest depth of axis beneath surface 150 ft.

Single track in horseshoe-shaped tunnel, lined with brickwork 5 to 6 bricks thick, or 26 to 31 ins., internal diameter at centre 15 ft., and internal height 19 ft. Backing of round stones found on the local hill slopes.

Tunnel Maintenance.—Cost of reinstating five 3 to 6-ring double-track railway tunnels, Clayton, Cliftonville, Balcombe, Rotherfield or Crowborough, and Mickleham, in chalk, clay, and sand, in the south of England, built between 1837 and 1875 and repaired between 1887 and 1917, including cutting out the inner ring and replacing by a brindle ring in cement, sometimes an additional ring, or part of the tunnel inverted, toe wall built to the footings, parts of the wall re-lined, or spaces behind walls and over arches filled with concrete, etc., the work being carried out day and night during traffic by contract or departmentally, a single line being run at night, and taking various periods of from three to eight years to complete.

11*l.* to 20*l.* per lineal yard.

Other tunnels requiring more extensive repairs, such as shoring, bad portions cut out, and completely rebuilt, use of cement gun, etc.

30*l.* to 250*l.* per lineal yard.

Water Towers.

Water towers, brick, exclusive of tanks and pipes, 1*s.* to 1*s.* 4*d.* per ft. cub., 2*s.* to 5*s.* per gal.
Water supply inside a building, including service pipes, taps, etc. 2*l.* 10*s.* to 3*l.* per tap.

Beverley Water Tower, Yorkshire (1915).—Built of reinforced concrete on the Hennebique system. Two circular tanks, one within the other, the inner one holding 4,000 gals. and the other

TUNNELS.

Tunnel.	Date.	Time to Construct.	Length.	Progress per Day of 24 Hours.	Total Cost.	Cost per Mile.	Cost per Yard Run.	Maximum Altitude above Sea Level.	Greatest depth of Axis beneath Surface.	Remarks.
	Years.	Years.	Miles.	Yds. Run.	£	£	£	Ft.	Ft.	
Arlberg .	1880–84	4	6⅓	9	1,204,000	190,100	108	4,300	1,600	In Austria. Two lines of track in single tunnel, 25 ft. 3 ins. wide × 21 ft. high, partly lined with masonry.
Mont Cenis	1857-71	14	7½	3	3,000,000	400,000	227	4,248	4,090	France to Italy. One tunnel, 26 ft. 3 ins. wide × 24 ft. 7 ins. high, with double track. Through solid granite, and lined with brick and stone.
Rotherhithe	1904–08	4	1⅛	1⅔	1,250,000	1,041,700	587	—	—	One tube, 30 ft. diameter. Top 7 ft. below bed of Thames. Fitzmaurice, engineer. 4,863 ft. between portals, and 1,400 ft. directly under the river. Max. progress in 1 day 10¼ ft.
Severn .	1877–86	13	4½	2	2,000,000	444,400	252	—	100	Width 26 ft. × 25 ft. high. Double track. Water-logged ground and expensive pumping. Hawshaw, Hayter, and Richardson, engineers.
Simplon .	1898–1905	7	12⅓	10	3,120,000	253,000	144	2,313	7,005	Switzerland to Italy. Two single-track tunnels, each 16 ft. 5 ins. wide × 19 ft. 6 ins. high, 56 ft. apart, axis to axis. Enlarged 1911, at a cost of 1,600,000*l.* A. Brandt, engineer.
St. Gothard	1872–82	10	9⅓	6	9,080,000	972,900	553	3,787	6,076	Switzerland to Italy. Two lines of way in a single tunnel, 26 ft. 3 ins. wide × 24 ft. 7 ins. high, in granite, lined with masonry. Louis Favre, engineer.
Thames .	1825–43	18	¼	⅛	482,000	1,928,000	1,300	—	—	Between Rotherhithe and Wapping. Brunel, engineer. Delay in completion due to water difficulties. Foot subway, with spiral stairways at each end. Used since 1866 as a tunnel by East London Electric Rly., and lengthened to 1⅓ mile.

It is generally cheaper to tunnel than to make a cutting over 50 ft. in depth, but a good deal depends upon whether earth is required for embankments, and upon the kind of ground.

7,200 gals., or a total of 11,200 gals. Extreme diameter 34 ft., and 10 ft. internal depth, with three 6-in. cast-iron outlets, 4-in. sides, 2-in. curved dome top, 4-in. bottom, with beams under, supported on three 12-in. × 12-in. columns or legs, 30 ft. high, with 12-in. × 8-in. braces to latter and half-way up. Total height from ground level to top of tank, 42 ft. 6 ins. Concrete foundations, 2 ft. deep. Cost, including materials and erection, 312*l.*, or 27*l.* 17*s.* per 1,000 gals.

Bramham Moor Water Tower, near Tadcaster, Yorkshire (1916).—Designed by the Trussed Concrete Steel Co. Two united rectangular tanks, 4,000 gals. and 6,000 gals., or a total of 10,000 gals.; two iron ladders inside the tanks for cleaning purposes, and 3-in. cast-iron outlets; 5-in. sides, 3½-in. flat top, 6-in. bottom, with 24-in. × 10-inch beams under, supported on four 10-in. × 10-in. columns or legs, 20 ft. high, with 10-in. × 6-in. braces to latter and half-way up. Foundations 2 ft. 6 ins. deep in addition. Cost, including materials and erection, 298*l.*, or 29*l.* 16*s.* per 1,000 gals.

Curragh Water Tower (1900).—Heavily built, 34 ft. square externally and 94 ft. high above ground. 6 stories. Concrete foundations 6 ft. thick, brick walls in cement 45 ins. thick below to 22 ins. at top. Flat concrete roof, asphalted. Contains two cast-iron tanks, 20,000 gals. each, or 40,000 gals. total. Lower floors used as a fire engine station. Building only, 9,300*l.*; cast-iron tanks and pipes, 1,630*l.*; special fittings, 70*l.* Total, 11,000*l.*

1*s.* 4*d.* per ft. cu. 275*l.* per 1,000 gals.

WATERWORKS.

Waterworks, comprising reservoirs, filter beds, mains, valves, hydrants, etc., complete:

	£	
Birmingham	3	per head of population.
Dublin	2	,, ,,
Edinburgh	3½	,, ,,
Glasgow	3	,, ,,
Liverpool	4	,, ,,
Manchester	3	,, ,,
Generally speaking	2*l.* to 4	,, ,,
Small waterworks in Ireland (20 to 25 gals. per head.)	2*l.* to 2½	,, ,,

Batticaloa Water Supply, Eastern Province, Ceylon (1915–16).—Supplies a population of 6,000 with about 20 gals. per head per day. One central well 10 ft. diameter, and two auxiliary wells same diameter, connected by adits 500 ft. long, yielding 180,000 gals. per day. From the central well the water is pumped through a 7-in. steel delivery main to the reservoir, 4 miles distant, from which the town is supplied by gravitation by 2-in. and 1½-in. distributing mains to 75 standpipes. 11¼ miles of pumping and service mains altogether. Pumping machinery in duplicate, 3-in. centrifugal pumps, belt-driven by 18 B.H.P. oil engines, each pump capable of delivering 10,000 gals. per hour against a total head of 60 ft., or a total pumping capacity of 100,000 gals. per diem working 10 hours. Wells lined with 12-in. concrete, roofed with concrete slabs. Storage reservoir of 100,000 gals., with concrete walls faced in brick cement rendered and roofed with corrugated iron on steel trusses. Cost, 9,533*l.*, or 95*l.* per 1,000 gals., or 1*l.* 12*s.* per head of population supplied.

New Magdalen Barracks Water Supply, Oxford (1896).—Supply from City of Oxford Water Company's mains, constant service, Siemens' meter supplied by Company. Davey's lift and force pump worked by steam power, and 6 in. cast-iron mains, 3 in. cast-iron domestic supply mains, and 1½ in., 1 in., ¾ in., and ½ in. galvanised wrought-iron service pipes, 3 to 4½ ft. deep. Reserve tank of 13,000 gals. for fire purposes, 60 ft. high on Armoury roof, 18 fire hydrants, 20 sluice valves, 40 stop valves, 280 bib valves, 50 3-gal. flushing cisterns to w.c.'s, and 6 200-gal. cisterns to latrines. Occupation of barracks, 500 adults, 100 children, and 5 horses. Total cost, including 800*l.* for machinery and erection, 3,500*l.*, or 5*l.* 16*s.* 8*d.* per head of occupation, exclusive of horses. 6*s.* 6*d.* per yd. run of excavation, exclusive of machinery, but inclusive of all fitments.

IMPOUNDING RESERVOIRS.

Impounding reservoirs for gravitation waterworks to large towns, including excavations, embankments, etc.

200*l.* to 700*l.* per million gallons storage.

	£	
Arnfield, for Manchester waterworks	432	per million gals. storage.
Crowden ,, ,,	561	,, ,,
Hollingworth ,, ,,	458	,, ,,
Tellowfold ,, ,,	722	,, ,,
Monmouth	912	,, ,,
Rooden, for Oldham	491	,, ,,
Sheffield waterworks, structures only	210	,, ,,
Ditto, including Parliamentary expenses, payments for compensation, etc.	485	,, ,,
Swansea	550	,, ,,
Swinshaw, for Ashton-under-Lyne and Stalybridge	405	,, ,,
Walshaw Dean, for Halifax	469	,, ,,

Curragh Old Waterworks Pumping Station.—Different dates, 1859, 1907, 1915, and 1921. Includes concrete reservoir, corrugated iron fence, brick engine house, boiler house, chimney shaft, workshop, coal yard, engineer's cottage, and new corrugated iron engine shed, engineer's hut, concrete tanks, old and new wells with bored Artesian tubes, 112 ft. and 276 ft. total depths respectively, barbed wire fencing, water-main connections, and 1,550*l.* worth of machinery, complete . . . . . 9,550*l.* total cost.

13½-in. Artesian bored tube well (1907), including boring 52 ft. deep sunk in sand and gravel from the bottom of existing dug well which is 8½ ft. diameter and 59 ft. deep . . . . . 3*l.* 5*s.* per ft. in depth.

Ditto including men's time, fixing plant, testing, and carriage, and hire of compressor . . . . . 7*l.* 10*s.* ditto.

(The cost of this Artesian well is included in the 9,550*l.* total.)

Curragh Old Waterworks Reservoir (1887–93). In connection with pumping station. Uncovered, with puddle clay embankments, stone-lined. Steel fence all round. Size, 320 ft. × 260 ft. × 6 ft. deep, and holds 3,100,000 gals. Total, 2,760*l.* 1½*d.* per foot cube. Reservoir now disused . . . . . 18*s.* per 1,000 gals.

Selby Waterworks Reservoir (1908). 800,000 gals. 12-in. concrete floor, brick walls, 50½ ins. thick at base and 22½ ins. at top, 6-in. concrete roof in arches of 7 ft. span. Total, 4,800*l.* . . . . . 6*l.* per 1,000 gals.

In the London Metropolitan area—

Cost of pumping averages 43 per cent. of the entire maintenance expenditure.
Cost of pumping alone averages 50*s.* per million gallons.
Repairs and renewals of water-mains and pipes, 34*s.* per million gallons.
Maintenance of water-mains or pipe-way, 24*l.* per mile.
Cost of filtration 7*s.* 5*d.* per million gallons.

Assuan Dam (1898–1902 and 1907–12).—The Assuan or Aswan Dam was built for irrigation purposes at the head of the first cataract of the Nile, about 600 miles from Cairo and 350 miles above the Assiout barrage. It was formed across 5 channels of the river, which flowed at the rate of 16 miles an hour, and constructed of local granite masonry in Portland cement, on a similar rock foundation which had dykes of softer igneous material. The original dam was 1½ miles or 6,600 ft. long, 100 ft. thick at bottom, tapering to 24 ft. at top, with a maximum height of 130 ft. from base. Total weight of stonework over a million tons: 180 sluice openings, closed by steel gates; 1,000 Europeans and 20,000 natives were employed. The barrier affected the Nile for 140 miles higher up, and turned it into a regular lake. The greatest difference of level of water above and below the wall was 67 ft., and navigation was provided by a ladder of five locks, each 260 ft. long and 32 ft. wide. This first dam was completed in 1902, and held about 250,000 million gallons, which brought over a million acres of desert under cultivation. Engineer, Sir Wm. Willcocks, and contractors, Sir John Aird & Co. Cost was 2,500,000*l.* constructional work and 2,000,000*l.* for land and compensation charges, or 4,500,000*l.* altogether. This latter is equivalent to 18*l.* per million gallons of storage capacity, or 4*l.* 10*s.* per acre of irrigation area.

Between 1907 and 1912 the foregoing original dam was raised an additional 23 ft., thickened by 16 ft. on the downstream side, lock walls widened, and new dock gates provided, so that the impounding reservoir or lake was now 240 miles long, and the storage capacity increased by an extra 310,000 million gallons. Another million acres were also brought under cultivation. The greater depth submerged the Philae temples well up the river. Sir Benjamin Baker was consulting engineer. Cost of extension, including land and compensation charges, was 1,500,000*l.*, equivalent to 4*l.* 17*s.* per additional million gallons, or 1*l.* 10*s.* per additional acre.

Total present capacity as enlarged, 560,000 million gallons, bringing two million acres under total irrigation, at a total cost of 6,000,000*l.* This is equivalent to an average of 10*l.* 14*s.* per million gallons, or 3*l.* per acre of irrigation, as finally completed.

Burrinjuck Dam (1909-20).—Or Barren Jack. The highest dam in the Empire and in the Blue Mountains of New South Wales, at the confluence of three rivers—the Murrumbidgee, the Goodradigbee, and the Yass, which the dam ponds up 40 miles, 13 miles, and 19 miles respectively. The artificial lake so created has a surface area of 20 square miles, or 12,800 acres, and is 220 ft. greatest depth, giving a capacity of over 33,000,000,000 cubic ft., or about 206,250,000,000 gallons. The dam is a massive wall in a deep gorge with cliffs 1,000 ft. high and only 300 yds. apart, the sides being so steep that it was impossible to establish workshops upon them, and it was also across the bed of a river subject to floods. The granite masonry is 236 ft. high from rock to crest, set in cement, and 186 ft. thick at base, tapering to 18 ft. at top. The dam is of the arch type with convex side turned up stream; radius of curve 940 ft. and length of arc 900 ft. Flood-water tunnel 14 ft. × 13 ft., and two culverts cut through the cliffs at the ends of the dam itself. The water had to be conveyed 260 miles, and then distributed by miles of canals

Various Towns.—Actual cost by pipe scraper driven by water pressure and supplied by Glenfield & Kennedy, Ltd., Kilmarnock:—

Year.	Place.	Diam. of Main.	Length of Main.	Total Cost.	Cost per Mile.	Cost per Yd. Run.	Obstructions removed, other than corrosion.	Gain in Delivery after Scraping.

over 1½ million acres of parched land, allowing the conservation of water for some 2,000 farms. Total cost about 3,000,000*l.*, or 14*l.* 11*s.* per million gallons of storage capacity, or 2*l.* per acre of irrigation area.

Croton Dam (1896–1911).—Or the Cornell Dam, which holds up the waters of the Croton River to form the great Croton lake reservoir which supplies New York with water, 33 miles away. A diversion canal, 1,000 ft. long and 2,000 ft. broad, was first excavated to divert the river before the dam itself could be commenced. The latter is about 1,200 ft. long, a maximum width of 216 ft., and greatest height 300 ft. from rock to crest, making it the highest in the world. It contains 833,000 cubic yards of masonry, and required 1,500,000 cubic yards of excavation. Owing to the rock being rotten, the foundations were carried in places 130 ft. below river-bed. Spillway built of granite blocks, some weighing 10 tons each. The lake behind the dam is 20 miles long, and contains 32,000,000,000 gallons of water. Three villages and numerous isolated buildings and farms were cleared away, and 75 miles of stone wall built round the reservoir. The outlay was excessive, as a large part was due to alterations and work which had to be afterwards undone, including the removal of the first core wall and taking up the earth on either side of it. Total cost about 1,600,000*l.*, or 50*l.* per million gallons of storage capacity.

Wentwood Reservior, Newport (1894–1904).—Situated at Llanvaches, some ten miles from Newport, Monmouthshire. It has a water area of 41 acres, a depth of 86 ft., and a capacity of 410,000,000 gallons. The great dam, which is 456 ft. above sea level, is 97 ft. high, 800 ft. long, and 700 ft. wide at base, gradually tapering to 30 ft. wide at top. The inside slope is pitched from top to bottom. The valve tower and outlet are placed quite independently of the dam at the eastern end, and the culvert, which runs for a length of 900 ft. through the dam, is 6 ft. diameter and carries two water mains. Water is drawn into the reservoir from two streams in the Newchurch valley by means of a tunnel, which ranges from 3 ft. diameter at the Newchurch end to 6 ft. at the reservoir end; length of tunnel, 3,683 yds. Total cost, about 390,000*l.*, or 951*l.* 4*s.* per million gallons of storage capacity.

Scraping Water Mains.

Ayr.—Scraping 14-in. and 16-in. cast-iron water mains, 14½ miles long, at Ayr, between Loch Findas and the service reservoir at Dalrymple, in 1915. Pipes laid 28 years before, but incrustation reduced capacity by 30 per cent. Scraper weighed 3 cwts., and was driven by a pressure of 15 ft. head of water. When this pressure was unobtainable the instrument was pulled through by a chain. Pipes were divided into sections with inspection boxes, and each section was done twice, the scraper travelling at the rate of 2 miles an hour. Capacity of mains was at once increased by 37 per cent.

For 14-in. pipes the scraping alone cost 13*l.* 8*s.* per mile, or 2*d.* per yd. run.
„ 16-in. „ „ „ 12*l.* „ „ 1⅜*d.* „
„ 14-in. pipes the total cost was 34*l.* 5*s.* „ „ 4⅜*d.* „
„ 16-in. „ „ „ 46*l.* 10*s.* „ „ 6¼*d.* „

Scraping is necessary every 3 years, owing to rapid reincrustation.

Prestwick.—Scraping 6 in., 8 in., and 10 in. water mains leading from the filters to the town, in 1923. In all 7,100 lin. yds. of pipes were scraped, and over 8 tons of corrosion removed. The pressure heads after scraping, as taken at air valves along the mains, showed an increase overall of 20 ft. The cost worked out at 1*s.* 5*d.* per yd. run.

Cleaning.—Cleaning 4 in. water main by the patent Powrcleer apparatus, supplied by the British Pipe Cleaning Co., W. &. J. Glossop, Hipperholme, Halifax, for a minimum quantity of 1,000 yds., 1*s.* 4*d.* per yd. run (August 1922).

SECTION XLIV

LEGAL NOTES FOR ENGINEERS

Contributed by W. Valentine Ball, O.B.E., M.A., Barrister-at-Law, A Master of the Supreme Court.

Author of 'The Law Affecting Engineers' Constable & Co.); 'The National Form of Building Contract' (published by The Local Government Journal), and Joint Editor of 'Emden's Building Contracts,' 4th Edition (Butterworth & Co.)

SECTION XLIV

LEGAL NOTES FOR ENGINEERS.*

(Contributed by W. Valentine Ball, O.B.E., M.A., Barrister-at-Law, A Master of the Supreme Court.)

(1) LEGAL STATUS OF AN ENGINEER. (2) FEES. (3) EMPLOYMENT OF AN ENGINEER. (i.) *Generally*; (ii.) *Employment Abroad*; (iii.) *Wrongful Dismissal*; (iv.) *The Restrictive Covenant*; (v.) *Engineers and Compensation for Accidents*; (vi.) *Engineers and the National Insurance Act*; (vii.) ***Effect of War on Contracts.*** (4) SECRET COMMISSIONS. (5) DISCLOSURE OF SECRETS. (6) RIGHTS OF AN ENGINEER TO THE INVENTIONS OF A SERVANT. (7) THE ENGINEER AS WITNESS. (i.) *Generally*; (ii.) *Arrangements as to Fees*; (iii.) *Evidence before Parliamentary Committees.* (8) LIABILITY FOR NEGLIGENCE. (9) RIGHTS, POWERS, AND DUTIES OF AN ENGINEER UNDER A CONTRACT FOR WORKS. (i.) *Generally*; (ii.) *Specifications*; (iii.) *Plans and Drawings*; (iv.) *Extras*; (v.) *Certificates*; (vi.) *Penalties and Bonuses*; (vii.) *Defects, Repairs, and Maintenance*; (viii.) *Subcontractors and Specialists*; (ix.) *Whether the Employer's Engineer can act as Arbitrator in Relation to Disputes Arising under a Contract.* (10) THE ENGINEER AS ARBITRATOR. (i.) *Generally*; (ii.) *Who may be Arbitrator*; (iii.) *Proceedings before the Arbitrator*; (iv.) *The Award*; (v.) *Time for Making the Award*; (vi.) *The Fees of an Arbitrator*; (vii.) *Stating a Case for the Opinion of the Court*; (viii.) *Costs of a Reference.* (11) NOTES ON SALE AND PURCHASE OF MACHINERY.

(1) LEGAL STATUS OF AN ENGINEER.

Any person may describe himself or practise as an engineer, as the word engineer is not a term of art in the legal sense. Although the Institution of Civil Engineers may make rules of professional etiquette to be observed by its members, compliance with such rules will not be enforced in a court of law, save in so far as they involve a restatement of the ordinary law. For instance a rule which states that no consulting engineer shall advertise could not be enforced, whereas infringement of a rule that 'he shall not pay by commission or otherwise anyone who introduces clients' might offend against the common law (*Panama Telegraph Co.* v. *India Rubber Co.* (1875) L. R. 10 Ch. 515) or against the Secret Commissions Act.

(2) FEES.

If an engineer is consulted, there is an implied contract to pay him reasonable remuneration (*Manson* v. *Baillie* (1855) 2 Mac. H. L. Cas. 80). It is more satisfactory, however, to provide for payment of fees beforehand. In the case of a contract to design and supervise erection of works it is well to provide for payment of $\frac{1}{3}$ on signing the contract, $\frac{1}{3}$ when half the contract price has been paid to the contractor, and $\frac{1}{3}$ when the contractor has been fully paid. Provision should also be made for (1) payment for plans and drawings in case the works are abandoned; (2) travelling and hotel expenses. There is, of course, no fixed scale of remuneration for the engineer, but in deciding what is a reasonable charge, the Court would have regard to (i.) the standing of the engineer; (ii.) the nature and extent of the work undertaken and carried out. It is no answer to a claim for fees (*a*) that a particular undertaking has proved to be a failure if the failure was not due to any fault of the engineer—as where, for instance, an engineer is employed merely to *supervise* the erection of a dam which bursts on completion; or where an engineer is employed to draw plans for a newly invented machine which fails to work (*aliter* if the employer was relying on the engineer's skill and judgment: *Duncan* v. *Blundell* (1820) 3 Stark. N.P. 6); (*b*) that the work in question is not completed, if the failure to complete is not due to the engineer. Where an engineer is to be paid on completion and the work is abandoned before the time, the engineer is entitled to what is due for services rendered, and to what he has lost by not being allowed to complete the contract (*Horton* v. *Hemsley* (1908) *Times*, February 19).

---

* See also 'LEGAL POINTS FOR ROAD ENGINEERS,' p. 789.

(3) EMPLOYMENT OF AN ENGINEER.

(i.) **Generally.**—Where an engineer is to be employed for more than a year certain, the agreement must be in writing; and this is so, even if the employment is terminable at any time by six months' notice on either side (*Hanau* v. *Ehrlich* (1912), A.C. 39). The document must set forth all the terms. It is safer, however, to have the terms of an agreement always put into writing. Special care should be taken to (*a*) specify the times when the salary is to be paid; (*b*) provide for the contingency of illness, as illness does not necessarily determine the contract, nor will it justify dismissal without regular notice, unless the employee is so smitten with disease that he can never be expected to work again (*Cuckson* v. *Stones* (1858) 1 E. & E. 248); (*c*) provide for the notice which may be given on either side to determine the contract. If nothing is specified in the agreement, an engineer employed at a yearly salary is entitled to a year's notice (*Buckingham* v. *Surrey and Hants Canal Co.* (1882) 46 L. T. 885). An engineer wrongfully quitting his employment without notice forfeits the salary due for the part of the current year which he has served. The fact that a contract of employment for an indefinite period contains no express term as to notice to be given for its determination does not exclude the implication that such a notice is required (*Payzu* v. *Hannaford* 34 T. L. R. 442). The suspension of servant from his duties which prevents his earning his commission may amount to a wrongful dismissal (*Rubel* v. *Vos*, 34 T. L. R. 171). Dismissal without notice is only justifiable in a case of gross misconduct. If the 'employer' is a company or a municipal corporation or other local authority it is safer to insist that the contract be under seal. The Public Health Act, 1875, s. 174 (1) provides that every contract made by an urban authority whereof the value or amount exceeds 50*l.* shall be in writing and sealed with the common seal of such authority. A surveyor who prepared plans for a local board under a verbal contract was held entitled to recover nothing (*Hunt* v. *Wimbledon Local Board* (1878) L. R. 4 C. D. D. 48). Close examination of a contract between an engineer and a local authority may, however, show that it is not within this section (see *Douglass* v. *Rhyl U.D.C.* (1913) 2 Ch. 407). Where the engineer is in the employment of a local authority he must have no interest in any contract into which that body enters (see *Melliss* v. *Shirley Local Board* (1885) L. R. 14 Q.B.D. 911). An attempt was recently made to raise the question whether a consulting engineer is liable to pay excess profits duty under s. 39 of the Finance Act, 1915, but the Court of Chancery refused to decide the point, leaving it to the King's Bench Division (*Smeeton* v. *Attorney-General* 35 T. L. R. 706).

(ii.) **Employment Abroad.**—Where an engineer is about to accept employment abroad, he should be careful to see that provision is made for the payment of travelling and other expenses. No agreement to pay travelling expenses would be implied from an undertaking, say, to employ an engineer at a salary of 1,000*l.* a year at Malacca as from January 1, 1913. It is also well to provide in the agreement that any disputes which may arise shall be determined either by arbitration or according to English law.

(iii.) **Wrongful Dismissal.**—If an engineer is wrongfully dismissed, it is his duty to reduce the damages as far as possible by taking other employment if he can procure it (see *Storey* v. *Fulham Steel Works* (1908) 23 T. L. R. 306). The damages are then ascertained by subtracting what he has earned from what he would have earned.

(iv.) **The Restrictive Covenant.**—When employing an assistant, an engineer may find it necessary to bind him not to set up close by in competition. A restrictive covenant is legal, if it is not too wide; it must be only what is reasonably necessary for the protection of the parties. A covenant to prevent a dentist practising within 200 miles of York was held to be too wide (*Horner* v. *Graves*, 7 Bing. 735). On the other hand, a covenant which bound a canvasser not to enter an employment 'within twenty-five miles of London where the plaintiffs carry on business' was held by the House of Lords to be unreasonable (*Provident Clothing and Supply Co.* v. *Mason* (1913) 29 T. L. R. 727). Care should be taken not to make the restriction perpetual unless that is absolutely necessary, for the Court criticises a perpetual covenant more closely (*Eastes* v. *Russ* (1915) 30 T. L. R. 237). In a recent case the validity of a covenant affecting a man who was employed as works engineer at a bottleworks was considered (*Forsters* v. *Suggett* 35 T. L. R. 87).

(v.) **Engineers and Compensation for Accidents.**—An engineer whose remuneration (e.g. money, board and lodging, etc.) amounts to less than 250*l.* in the service of an employer is probably entitled to the benefits of the Workmen's Compensation Act, 1906.

(vi.) **Engineers and the National Insurance Act.**—A nice question may arise as to whether, say, a station engineer must be treated as an employed contributor within the meaning of the National Insurance Act, 1911. That act covers employment in any contract of service subject to the proviso that persons earning more than 160*l.** otherwise than in manual labour need not be insured. It is submitted that the station engineer earning less than 160*l.* must be insured, but that the consulting engineer who receives an annual fee of 100*l.* for advising a firm or company need not be insured. His is a contract not 'of service' but 'for services'—a distinction which has been drawn in the Court of Appeal.

* By the National Health Insurance Act, 1919, now raised to 250*l.*

(vii.) **Effect of War on Contracts.**—Contracts entered into during the war, between British citizens and the citizens of States at war with Great Britain, were illegal and could not be enforced, unless a licence to trade was granted to one of the belligerents. Subject, however, to certain exceptions, contracts entered into by the citizens of one belligerent State with citizens of another belligerent State before the outbreak of hostilities between their respective states are not dissolved by the outbreak of war but suspended until the war is over. During suspension no performance of the contract is permitted, nor will any action on it be entertained in English Courts, even though the cause of action arose before the war. But the war being now over the mutual obligations of performance and the rights of action revive. The exceptions are (*a*) Contracts entered into before the outbreak of hostilities which will inure to the aid of the enemy or which involve any dealing with the enemy (see *Furtado* v. *Rogers*, 3 Bos. & P. 91); and (*b*) Contracts entered into before the outbreak of hostilities which from their nature cannot be merely suspended (*Griswold* v. *Waddington* (1818) 16 Johnson's Rep. 438).

(4) SECRET COMMISSIONS.

The receipt of a secret commission or a bribe by an engineer would clearly justify his dismissal (*Boston Deep Sea Fishing Co.* v. *Ansell* (1888) 39 Ch. D. 339). In such a case there is a presumption that he was influenced, against his employers' interest, by the bribe (see *Hovenden* v. *Millhoff* (1900) 83 L. T. 11).

(5) DISCLOSURE OF SECRETS.

An engineer may be employed to do work of a confidential nature for others; or he may have to employ workmen to do confidential work for him (e.g. by employing a workman to make a model of a new and patentable machine). The law implies an agreement by the servant to keep his master's secrets, and he may be restrained by injunction from disclosing them (*Alperton Rubber Co.* v. *Manning and Others* (1917) 116 L. T. 499; 33 T. L. R. 205).

(6) RIGHTS OF AN ENGINEER TO THE INVENTIONS OF A SERVANT.

If a servant invents a machine in his employer's time and even when using his employer's materials, the invention does not become the property of the employer so as to prevent the servant taking out a patent for it (*Heald's Case*, 8 R. P. C. 430). But if the servant were to steal an idea and endeavour to patent it either before or after the termination of the service, the employer could oppose the grant of a patent in respect of it (*Thwaites' Application*, 9 R. P. C. 515). And if the servant obtains a grant of a patent in respect of the invention, he can only hold it as trustee for his employers (*British Reinforced Concrete Engineering Co.* v. *Lind* (1917) 33 T. L. R. 170). The engineer when employing a servant should take care to provide, by the agreement, that the inventions of the servant shall belong to him; but when himself entering into a contract of service he should be careful to sign nothing which will abrogate his rights.

(7) THE ENGINEER AS WITNESS.

(i.) **Generally.**—As the engineer frequently comes into contact with the law and the lawyers in the capacity of a *witness*, a few notes of a practical character on the duties of a witness may be found useful.

When invited to give evidence as an expert the engineer should: (*a*) arrange for a qualifying fee to be paid in any event; (*b*) examine the plans and documents, and, if necessary, obtain a view of the *locus in quo* before consenting to give evidence; (*c*) warn the parties consulting him of all the difficulties which are manifest to him; (*d*) ascertain, if possible, the contentions which are going to be put forward by the other side, and make himself familiar with any views which they may have published upon the matters in dispute. Having consented to give evidence, the engineer should (*a*) be ready to satisfy the lawyers with regard to any technical point which may be raised in consultation; (*b*) listen to the arguments and evidence in Court, and be prepared to deal with any points made by witnesses on the other side; (*c*) bring with him any entries in his diary or any notes which he may have made *at the time* with reference to the matters in dispute, for he may use such notes to refresh his memory. Thus, if an engineer has to report as to the condition of a structure, he may use in the witness box the notes which he made on the spot. But he could not use a copy of such notes unless he was prepared to produce the original; (*d*) make and bring to court a plan or model of the structure or machine under discussion, as this will save much wordy explanation; (*e*) search in libraries and in the published proceedings of the various institutions for any books and papers dealing with the matters in hand—especially any papers written by himself, in order that he may not be confronted with an adverse opinion given on a former occasion. A witness should bear in mind that it is his duty to state facts and express opinions, not to advocate the cause. As soon as he appears to be taking a biased view or attempting to fight the case it is more than likely that the tribunal will pay little heed to his evidence. A candid answer to an awkward question is often less dangerous than a long and evasive statement. In *Crosfield and Sons, Ltd.* v. *Techno-Chemical Laboratories Ltd.* (1913, 29 T. L. R. 378) Neville, J., expressed some views as to the function of an expert witness which may be thus summarised:—

(*a*) It is not competent in any action for witnesses to express their opinion upon any of the issues, whether of law or fact, which the Court or a jury has to determine.

(*b*) In patent cases, expert evidence is often necessary (i) to explain words or terms of science or art, or to inform the Court in case the import of a word in a document to be construed differs from its popular meaning; (ii) to instruct the Court in the laws of science; (iii) to describe the state of public knowledge at the date of the patent. 'It is rare,' added his lordship, 'to find any substantial difference of opinion between eminent experts upon matters of science whenever it is possible to dissociate the question from immediate connection with the issues in the action.

(ii.) **Arrangements as to Fees.**—On being *subpœnaed* one is bound to attend as a witness provided sufficient conduct money is paid with the subpœna. Failure to attend might lead to an action for damages, while in the County Court the judge has power to fine a witness for non-attendance. A witness may refuse to give evidence until his expenses have been paid (*Newton* v. *Harlund* (1840) 1 M. & G. 956). It should be noticed that the person liable to pay the fees is the party to the litigation, not the solicitor, unless he has expressly made himself liable (*Lee* v. *Everest* (1857) 26 L. J. Ex. 334). In order to save trouble it is best to arrange for and if possible secure payment of fees in advance. The fees 'allowed on taxation,' that is to say, the fees which an unsuccessful litigant will be ordered to pay in respect of witnesses called by the other side, are very small, but the party calling the witness will have to pay his agreed fee whatever it is. Where a case is tried at assizes in the town where the engineer lives or in London (when the engineer lives in London), the fee allowed is 1*l.* 1*s. per diem*, or where the engineer lives away from the town 1*l.* 1*s.* to 3*l.* 3*s.* But the taxing masters may also allow a qualifying fee of so much a day varying with the magnitude of the case. In 1875 a fee of 7*l.* 7*s.* was not considered excessive payment to a scientific witness. It is probable that a larger sum would be allowed at the present day. In addition he is allowed the travelling expenses reasonably and actually paid. In County Courts the fee allowed for qualifying to give evidence on Scae B is 1*l.* 1*s.* to 3*l.* 3*s.*; on Scale C, 1*l.* 1*s.* to 5*l.* 5*s.*; for attending Court on trial (*per diem*), Scale B, 1*l.* 1*s.* to 2*l.* 2*s.*; Scale C, 1*l.* 1*s.* to 3*l.* 3*s.*

The above scales were fixed before the war, and have not been altered. So far as they can the taxing masters will probably grant the maximum owing to high prices.

(iii.) **Evidence before Parliamentary Committees.**—When an engineer is summoned to appear as a witness before a committee of either House of Parliament he looks for his fees to the party who summons him—whether he is the promoter or an opponent. According to May's 'Parliamentary Practice' (1906) p. 434, an engineer summoned as a witness before a committee should report himself to the committee clerk on his arrival in London, or he will not be allowed his expenses for residence prior to the day of making his report; 3*l.* 3*s.* a day is the parliamentary allowance, but of course as between the engineer and the party summoning him the *quantum* of the fee is a matter of agreement.

(8) LIABILITY FOR NEGLIGENCE.

The liability of an engineer for negligence is similar to that of any other professional man. To render him liable it is not enough that there has been a less degree of skill than some other professional man might have shown. A fair average degree of skill is all that can be insisted upon (*Lamphier* v. *Phipos* (1838) 8 Car. & P. 475). If an engineer were so careless in the preparation of a tender that the cost of the works was grossly underestimated, he would probably be liable to pay damages, and he certainly could not recover his fees (*Moneypenny* v. *Hartland* (1826) 2 C. & P. 379). An engineer should be acquainted with any local bye-laws appertaining to the work in hand (*Monks* v. *Dillon* (1884) 12 L. R. Ir. 321). On the principle of *respondeat superior*, an engineer is responsible for the acts or defaults of assistants employed by him (*Mackersy* v. *Ramsays* (1842) 9 C. & F. 818). The question 'To whom is the engineer liable for negligence?' depends upon the conditions of employment. If he is engineer in relation to a large contract, he is not liable for anything done by him in his capacity as arbitrator between the employer and the contractor; but he is liable for damage resulting from negligence in supervision, e.g., failure to examine and test work before it is hidden from view (*Leicester Guardians* v. *Trollope* (1911) 75 J. P. 197). The contractor, however, could not sue the engineer for an error in the specifications on the basis of which he made his tender. Where, however, the 'quantities' are prepared by the engineer, and his fees for their preparation are paid by the contractor, it is conceived that he could be sued for damages resulting from an error in those quantities (*Bolt* v. *Thomas*, 'The Law Affecting Engineers,' p. 58). If an engineer order extras without authority, the contractor may possibly sue him for damages for breach of warranty of authority (*Randall* v. *Trimen* (1856) 18 C.B. 786). The amount of damages recoverable for negligence is to be measured by the loss which the plaintiff has suffered. In *Saunders* v. *Broadstairs Local Board* (1890) 2 H. B. C. 160, two engineers claimed fees for preparing surveys, obtaining tenders, and superintending the execution of a contract for certain drainage works. The board counterclaimed for negligence and were awarded 2,046*l.*, the amount overpaid to the contractor by reason of the negligence of the engineers in over-certifying the quantities; 2,400*l.* estimated cost of doing bad work over again; 240*l.* actual cost of repairs already done to defective work. Damages recovered by a workman against his employer for an accident might also be recovered from the engineer if it were shown that the accident was caused by the engineer's negligence (*Mosdell* v. *Mitchell*, 'Times,' January 20, 1891).

(9) RIGHTS, POWERS, AND DUTIES OF AN ENGINEER UNDER A CONTRACT FOR WORKS.

(i.) **Generally.**—Common forms of contract for large works usually set forth the powers, etc., of the engineer very clearly. The preparation of the contract is generally left to a lawyer, but the engineer should be on his guard against allowing a common printed form to be applied indiscriminately to the construction of works of a special nature. When difficulties arise it may be found that the common form does not provide for their elucidation.

(ii.) **Specifications.**—The contract should contain a clause providing that the employer will not be responsible for any mistakes or inaccuracies in the specifications which form part of the contract. Such a clause will, in the absence of fraud, afford him protection (*Pearson* v. *Dublin Corporation* (1907) A. C. 357). There should also be a clause calling the would-be contractor's attention to the fact that he must make surveys and borings for himself before making his tender. In that case, if unforeseen difficulties are met with the employer will not be responsible (*Thorn* v. *Mayor of London* (1876) L. R. 1 A.C. 120). Again, where a man undertakes to make e.g. sound hydraulic cylinders according to a specification, capable of withstanding a certain pressure, he takes upon himself the risk of the cylinders being able to withstand the named pressure when made according to the specification (*Hydraulic Co.* v. *Spencer* (1886) 2 T. L. R. 554). Carelessness in the preparation of a specification may involve the employer in added expense, for which the engineer may be liable (*Moneypenny* v. *Hartland* (1828) 2 C. & P. 378).

(iii.) **Plans and Drawings.**—These form part of the contract, and may, in the absence of a disclaiming clause, operate as a warranty that dimensions, measurements, etc., are correct. A clause disclaiming responsibility for accuracy should therefore be inserted in the contract. The engineer has no implied authority to alter plans and drawings so as to increase or lessen the burden imposed upon the contractor (*Cooper* v. *Langdon* (1841) 9 M. & W. 60). Delay in supplying the necessary plans and drawings may excuse the contractor from carrying out the work within the contract time (*Roberts* v. *Bury Commissioners* (1869) L. R. 5 C. P. 310). It is for the engineer who prepares them to see that they conform to local bye-laws (*Cubitt* v. *Smith* (1864) 11 L. T. 298). Plans and drawings made for the purpose of carrying out works are the property of the employer—not of the engineer (*Gibbon* v. *Pease* (1905) 1 K.B. 810). As to copyright in plans, see the Copyright Act, 1911, s. 5.

(iv.) **Extras.**—The duty of deciding what are 'extras' within the meaning of the contract is usually entrusted to the engineer. He has no implied authority to order extras (*Cooper* v. *Langdon* (1841) 9 M. & W. 60), although an agreement to work *to the satisfaction* of an engineer has been held to give him implied authority to order extras (*Robertson* v. *Jarvie* (1910) 45 S. L. R. 260). It has been held, however, that where the plaintiffs were employed by an architect (whose functions, for this purpose, correspond to those of an engineer) to supply door handles and door furniture for a building, and shortly before the delivery of the goods he informed the defendants, who were the builders, that the goods were being supplied by the plaintiffs, the defendants who used the goods in the building were liable to pay for them (*Ramsden* v. *Chessum* (1914) 78 J. P. 49). Extras should be authorised in the manner provided by the contract, which usually provides that all extras shall be ordered in writing (*Russell* v. *Saida Baudeira* (1862) 13 C. B. N. S. 149); but, in the case of a contract with a local authority, which must be under seal, the order for extras need not be under seal (*Williams* v. *Barmouth Urban Council* (1897) 77 L. T. 383). If a written certificate is rendered necessary by the contract, nothing else will suffice; but in a recent case a contractor proceeded with extra work as required by an engineer without any written order. On his claiming payment, an arbitrator found that the engineer was wrong and unreasonable, and that the work and materials required by him were not included in the contract. After much litigation the House of Lords eventually held that this decision was correct (*Brodie* v. *Cardiff Corporation* (1919) 120 L. T. 417). Although the whole scheme of works cannot be altered by virtue of the extra clause (*R.* v. *Peto*, 1 Y. & J. 37) power to *vary* the work will give the engineer authority to substitute one piece of machinery for another of which it is well known to be the mechanical equivalent (*Stevens* v. *Mewes & Davies*, Court of Appeal, June 7, 1910; Emden's 'Building Contracts,' Supplement 1911). The engineer should therefore see that he has power to *vary* the work. The engineer's decision as to what are extras may or may not be subject to revision in accordance with the arbitration clause. So far as the contractor is concerned, the fact that the engineer has given his final certificate (see *sub. tit. Certificates, post*) may involve a final decision as to what is and what is not an extra (*Connor* v. *Belfast Water Commissioners* (1871) 5 L. R. Ir. C. L. 55). Power to extend the time for completion is generally given to the engineer. It may be that owing to the action of the Government acting under the Defence of the Realm Acts, the performance of a contract for works becomes illegal during the continuance of the War. In such a case it is conceived that no extension of time by the engineer will avail to keep the contract alive (see *Metropolitan Water Board* v. *Dick, Kerr & Co.* 34 T. L. R. 111).

(v.) **Certificates.**—It is the duty of an engineer in relation to a contract for large works to grant or withhold the certificates upon which the contractor is paid. 'Progress certificates' are given from time to time as the work proceeds. They generally authorise payment to the extent of

80 per cent. upon the contract value of the work done from time to time. The remaining 20 per cent. is kept back usually, as to 15 per cent. until the final certificate is granted and as to 5 per cent. until the end of some stated period after the final certificate. This 20 per cent. is called the retention money (see *West Yorkshire Bank Ltd.* v. *Isherwood Bros.* (1912) 28 T. L. R. 593). The 'final certificate' is granted when the work is finished to the satisfaction of the engineer, and the contractor can sue for nothing until it has been granted (*Wallace* v. *Brandon and Byshottles U.D.C.* (1903) 2 H. B. C. 392). In deciding as to certificates the engineer acts as an arbitrator, and his decisions cannot be called in question (*Wadsworth* v. *Smith* (1871) L. R. 6 Q.B. 332); nor can he be compelled, and is better advised not to give reasons for his decision (*Stevenson* v. *Watson* (1879) L. R. 4 C. P. D. 148). No action lies against him for negligence in relation to certificates (*ib.*) (but see the case of *Goddard* v. *Ferguson*, *infra*). In exercising his discretion he must act as an arbitrator between employer and contractor (*Chambers* v. *Goldthorpe* (1901) 1 K.B. 624). It may, however, be that the decision of the engineer as to a certificate is subject to the arbitration clause, which has been held to be the case in relation to the form of contract approved by the Royal Institute of British Architects (*Robins* v. *Goddard* (1905) 1 K.B. 294). A fraudulent agreement between the employer and the engineer would however affect the validity of a certificate (*Kellett* v. *New Mills U.D.C.* (1900) 2 H. B. C. 330). The certificate of the engineer may be made a condition precedent to the contractor's right of action against the employer. If so an action cannot be maintained unless there has been improper dealing between the engineer and the employer (*Eaglesham* v. *McMaster* (1920) 2 K. B. 169). The statement that an engineer is not liable for negligence in relation to a certificate does not appear to be supported by the case of *Goddard* v. *Ferguson* (referred to by Mr. Saxon Snell in a paper read by him at the Royal Institute of British Architects, April 15, 1912). It was there held that an architect who grants a certificate which is successfully challenged by an employer in an action brought against him by a builder to recover the amount so certified to be due to him, is liable to repay to the employer the costs incurred by him in resisting the builder's claim. The Official Referee held the architect liable on the ground that when acting as agent for the building owner in granting certificates, he must be held responsible for the reasonable and probable consequences of giving a certificate subsequently held to be inaccurate or excessive. Certificates should always be given in writing in a formal manner. No engineer should pass any contract which does not contain a provision to this effect. As to when an engineer is disqualified from granting certificates, see paragraph ix., *infra*. An engineer has no right to delegate the power to grant a certificate to a subordinate, e.g. to the resident engineer (*Freeman & Sons* v. *Middleton Electric Traction Co.*, per Hamilton, J., July 15, 1910; Court of Appeal, January, 1911; Emden's 'Building Contracts,' Supplement, 1911).

(vi.) **Penalties and Bonuses.**—The question whether the contractor must pay penalties or not depends almost entirely upon the engineer. Penalties are imposed if the work is not carried out in accordance with the provisions of the contract as to time. The fact that extras are ordered will excuse the contractor from compliance with the conditions as to time (*Dodd* v. *Churton* (1897) 1 Q.B. 562), but the jurisdiction of the engineer does not extend to deciding this point (*Gallivan* v. *Killarney Urban Council* (1912) 2 Ir. R. 356). To avoid complication, however, it is best to insert a clause in the contract giving the engineer power to extend the time. With regard to the penalty clause generally nice questions sometimes arise as to whether it is capable of enforcement. If it is unreasonable on the ground that the punishment is too severe, the Court may refuse to enforce it; and it is for this reason that the words 'the sums to be regarded as liquidated damages and not as a penalty' are usually inserted after the sum named. The breach of an engineering contract involves damage of so uncertain a nature that the courts will generally treat the sum which the parties themselves have named as liquidated damages. Penalties will not be imposed if (*a*) the delay was caused by the act or default of the employer (*Thornhill* v. *Neats* (1860) 8 C. B. N. S. 831); (*b*) if there is delay in setting out the site or in delivering plans (*Roberts* v. *Bury Improvement Commissioners* (1870) L. R. 5 C. P. 310). The fact that the contractor has been delayed by a strike of his workmen, however, affords no excuse for delay (*Budgett* v. *Rimington & Co.* (1890) 25 Q.B. D. 320), nor, apparently, is the employer to be held liable for the acts of third parties causing delay (*Porter* v. *Tottenham U.C.* (1915) 1 K. B. 776). While a penalty clause is usually optional, it is obligatory in contracts made with certain local authorities (see Public Health Act (1875) s. 174 (2)). A bonus clause is sometimes inserted by virtue of which a contractor is enabled so much extra for expedition. If a contract contains such a clause, and the engineer has power to extend the time, it seems that his power to extend must be exercised not to enable the contractor to earn the bonus but only to avoid penalties (*Ware* v. *Lyttelton Harbour Board* (1882) 1 N. Z. R. 191).

(vii.) **Defects, Repairs, and Maintenance.**—In contracts relating to the erection of machinery clauses should be inserted providing for any defects which appear either before or after the issue of the final certificate. A useful form of this clause will be found in the printed conditions of contract issued by the Institution of Electrical Engineers. Its importance will be recognised when it is pointed out that when it is absent the final certificate of the engineer may possibly bar any further claim by the employer (*Lord Bateman* v. *Thompson* (1875) 2 H. B. C. 23). The time for the remedy of defects should be prolonged as much as possible, inasmuch as the very fact of there being a defects clause impliedly releases the contractor from liability for defects appearing after the stated time (*Sharp* v. *Great Western Railway Co.* (1841) 11 L. J. Ex. 17). The contractor can only be called upon to repair and maintain when compelled to do so by a repairing clause and a maintenance clause. The employer must give notice of want of repair. Mainten-

ance should be provided for in cases where the machinery or work is of a special character which is best known to the contractor. In the absence of any clause relating to defects and maintenance, it does not follow that on payment of the full price the employer thereby waives all claim for damages for work improperly done. It is a question of fact having regard to all the circumstances of the case whether the settlement was final and complete.

(viii.) **Subcontractors and Specialists.**—Most modern contracts involve the employment of subcontractors or specialists. A clause should be inserted in the head contract prohibiting the employment of any subcontractor or specialist unless approved by the engineer. In the absence of such a clause, the contractor might, possibly, farm out portions of the work to all and sundry (*British Waggon Co.* v. *Lea* (1880) 5 Q.B. D. 149). The engineer, apparently, has no implied authority to employ subcontractors (*Cowan* v. *Goderich* (1859) 10 U. C. C. P. 87). It is often well to specify the names of manufacturers of the raw materials which are to be used in the body of the contract. In order to preserve his right to supervise the work of any subcontractor or specialist, the engineer should secure the insertion in the head contract of a clause providing that payments to subcontractors shall be made by the contractor only upon the certificates of the engineer. It is also well to secure the insertion of a clause to the effect that, in the event of the contractor becoming insolvent, the subcontractor or specialist may be paid directly by the employer. All responsibility for delay or negligence on the part of a subcontractor is generally, by a special clause, placed upon the contractor (see, generally, *Crittall* v. *L. C. C.* (1910) 75 J. P. 203; *Hampton* v. *Glamorgan County Council* (1916) 115 L. T. R. 426, and the case of *Ramsden* v. *Chessum*, cited, *supra*, s. (9) (v) (L)).

(ix.) **Whether the Employer's Engineer can act as Arbitrator in Relation to Disputes Arising under a Contract.**—The position of the engineer in relation to a large contract has been rendered very difficult by certain recent decisions of the courts. In theory he is agent for the employer in the preparation of plans and specifications and in the supervision of the work, and he is arbitrator or *quasi* arbitrator between the employer and contractor in granting certificates, approving work done, granting extensions of time, etc. Sometimes he is made sole arbitrator to decide all disputes between the employer and the contractor, and a serious question has arisen in several recent cases as to how far a contractor can be forced to accept his decision whether in the matter of granting certificates, etc., or as arbitrator. In *Jackson* v. *Barry Railway Co.* (1893) 1 Ch. 238, it was held that the fact of the employer's engineer having expressed a view of the matter in dispute hostile to the contractor was not a sufficient justification for refusing to allow him to act as arbitrator in relation to that dispute. The Court of Appeal pointed out that the contractors had agreed to this form of reference, and what they relied on was the professional honour, practice, and intelligence of the engineer. There was nothing in the circumstances of the case to render it improbable that he would not arrive at an honest decision.

In *Ives* v. *Willans* (1894, 2 Ch. 478) the same result was arrived at, although in giving judgment Lord Justice Davey said: 'No doubt in a sense the engineer will be the judge of his own conduct, and no doubt that is a position which *prima facie* raises some surprise in a judicial mind; but that is the contract of the parties.' As already indicated later decisions appear to have practically altered the law, although the judges always took care to say that *Ives* v. *Willans* is still good law. The result of the recent cases may be thus summarised. A contractor will not be bound to submit to the arbitrament of the employer's engineer (*a*) if the matter in issue is an unseemly personal dispute raising a vindictive feeling between the engineer and the contractor, and the engineer has so strongly expressed his view that it amounts to a prejudgment (*Nuttall* v. *Manchester Corporation* (1893) 8 T. L. R. 513); (*b*) if the nature of the dispute is such that the cross-examination of the engineer is essential (*Freeman* v. *Chester R. D. C.* (1911) 1 K.B. 783); (*c*) if the matter in issue is something outside the original agreement, e.g., a dispute as to whether the engineer and contractor had agreed to vary the original agreement (*Aird* v. *Bristol Corporation* (1913) A. C. 241); (*d*) if the conduct of the engineer himself is practically the only point in dispute (*Blackwell* v. *Derby Corporation* (1909) 75 J. P. 129). Finally, it was held in *Roberts* v. *Hickman* (1913) A. C. 229 that the grant of a certificate by an architect will not be a condition precedent to the builder's right to sue if, by writing letters to the employer, and allowing himself to be influenced by their views, the architect has disqualified himself from acting judicially although guilty of no fraud or improper conduct.

If the method of arbitration provided for in many existing forms of contract is declared to be impossible for any of the above reasons the only alternative is litigation, a method of settling disputes which employers, contractors, and engineers always seem to desire to avoid. What can be done to avoid such a calamity in relation to future contracts? The following courses are open. Insert a clause (*a*) referring all disputes to an arbitrator to be mutually agreed or to be nominated by the president of one of the Institutes (see, e.g., the form approved by the Institution of Electrical Engineers, clause 47); or (*b*) referring disputes to a *named* arbitrator; or (*c*) refer disputes to the president of one of the Institutes whoever he may be. The first of these suggestions appears to offer the best practical solution of the difficulty. The writer, however ventures to make the following suggestion which might possibly work in practice. Frame the arbitration clause so as to leave the decision of every question arising under the contract to the engineer but subject to a proviso that should it appear to the Court on an application to stay any action or proceeding brought in relation to the contract that the engineer is disqualified from acting as arbitrator the matters in dispute will be referred to an engineer to be agreed between

the parties, or failing agreement to be nominated by the president of the Institution of Civil Engineers. Another alternative is suggested by Mr. E. J. Rimmer in his Arbitration Clause in Engineering Contracts' (Constable & Co.). It is that a proviso should be added to the arbitration clause stating that if any action is brought the defendant may either (*a*) have the action stayed or (*b*) have the matter referred to an independent arbitrator appointed in one or other of the manners above suggested.

(10) THE ENGINEER AS ARBITRATOR.

(i.) **Generally.**—Engineers are frequently called upon to act as arbitrators to decide disputes of a technical nature wholly unconnected with any contract in which the engineer has been employed. Arbitrations are conducted in accordance with the provisions of the Arbitration Act, 1883. An arbitrator may be appointed (*a*) by the Court ; (*b*) by the terms of the contract itself ; or (*c*) by a person nominated for that purpose in the contract, e.g., the president of the Institution of Civil Engineers. As to appointment by the Court, this occasionally takes place when a prolonged scientific enquiry is necessary. A 'referee' of this kind may have power either to wholly dispose of the dispute or make an enquiry and report to the Court, in which latter case the Court itself gives the judgment after considering the report. As references of this kind are rare in practice they will not be further dealt with.

As a rule the engineer finds himself made arbitrator pursuant to the arbitration clause in an agreement. Any dispute arising under any contract may thus be referred, and the parties will as a general rule be bound to proceed to arbitration for the purpose of settling a dispute instead of bringing an action at law. Where a contract contains an arbitration clause, if one party commences an action, the other may apply to the Court to stay the action pending a reference, and the action will generally be stayed, unless there is some good reason for not allowing the arbitration to proceed. For instance, in a recent case a contractor alleged that he had been induced by fraudulent representations as to the nature of the soil to enter into a particular sewerage contract, and brought an action for fraudulent misrepresentation. It was held that such an action ought not to be sent to arbitration (*Monro* v. *Bognor Urban District Council* (1915) 84 L.J. K. B. 1091). (See also par. 9, ix. *supra*.)

(ii.) **Who may be Arbitrator.**—Any person upon whom the parties agree may act as arbitrator. Thus if in contract with a local authority it is specified that the borough engineer shall be arbitrator there is no objection to his so acting, and the contractor can be compelled to accept his award (*Ives* v. *Willans*. *supra*, 2 Ch. 478). That is the broad rule, but the Court, as has been shown, always has power to refuse to enforce the arbitration clause in a case where it is obvious that the arbitrator ought not to act owing to bias, etc. Frequently the clause provides for the appointment of an arbitrator by each party with power to the arbitrators in case of differences to appoint an umpire. When this is done the umpire and arbitrators generally find it convenient to sit together to decide the case.

(iii.) **Proceedings before the Arbitrator.**—Witnesses must be sworn in the usual way. Due notice must be given to either party of the time when it is proposed to hold the sitting. In a case of great complexity it is well to have a preliminary sitting in order to require the parties to formulate the points in difference between them. By this means the issues may be considerably narrowed. The arbitrator should hear both sides, who may be represented by solicitor or counsel. He must never hold private communication with one party on the subject matter of the reference. He has no power to examine witnesses in the absence of the parties. An arbitrator who takes evidence in the absence of, and without notice to, a tenant, is guilty of legal misconduct, for which his award may be set aside (*In re O'Connor*, 88 L. J. K. B. 1242); *Ramsden* v. *Jacobs* (1922) 1 K.B. 640). It is for the arbitrator to decide every question whether of law or fact. He may, however, consult a solicitor or, for that matter, any other expert on legal points. Indeed the writer was recently concerned in a case in which, with the consent of the parties, the arbitrator had his solicitor sitting by his side. He should take full notes of the evidence, unless, as is frequently the case, the parties agree to have a shorthand note.

(iv.) **The Award.**—If the case is complex, the engineer is well advised to consult his solicitor as to the form of the award. The following are the features of a valid award, which should be in writing. (*a*) *It must not exceed the submission.* Thus if the question submitted was whether the stone used for building a dam was according to specification, the arbitrator would have no power to award that the stone used was better than as specified and that the employer must pay for it. (*b*) *It must extend to all matters in dispute.* If several distinct questions are referred and the arbitrator omits to decide upon any one of them, the whole award is bad. If in the case mentioned he were asked to decide (i.) was the stone as specified ; (ii.) was it suitable for the purpose, he would have to decide both questions. (*c*) *It must be certain.* The award must be so framed that its meaning is clear to the parties ; but according to a legal maxim, that is certain which is capable of being rendered certain. Thus to award that A. and B. shall pay a debt in the proportion in which A. and B. hold shares in a ship is a sufficiently definite award (*Watson* v. *Watson* (1671)

Sty. 28). (*d*) *It must be final.* The award must peremptorily state the arbitrator's finding. A mere expression of opinion that A. ought to pay B. such sum as C. thinks proper would not be a final award. Finally (*e*) *it must not be impossible, unreasonable, inconsistent,* or *illegal.* An award which directed that one party should do something illegal, e.g. trespass upon the land of another would be invalid.

(v.) **Time for Making an Award.**—In the absence of agreement, an award must be made (*a*) within three months of the date of entering on the reference, or (*b*) within three months after having been called on to act by notice in writing from one of the parties, or (*c*) on or before any later day to which the arbitrator may by writing under his hand extend the time for making the award (Arbitration Act, 1889, Schedule 1 (c)). The power to extend the time is important in the case of a long and complicated reference, but it must be exercised within the period of three months above referred to. Unless the arbitrator extends the time, or the parties agree to allow him to do so, an application must be made to the Court to extend the time; and such an application may be made whether the time for making the award has expired or not (*ib.*, s. 9).

(vi.) **The Fees of an Arbitrator.**—The arbitrator should name his fee beforehand. It is best fixed at so much *per diem* for the hearing. If no preliminary arrangement is made, he is entitled to charge what is fair and reasonable, and he can keep back his award until the fees are paid (*Ponsford* v. *Swain*, J. & H. 433). When deciding in the award as to costs he should state who is to pay his fees; but he may insist upon their being paid by the party who takes up the award. He should not reveal his decision until after these formalities have been observed. Sometimes the *quantum* of an arbitrator's fees is left to the decision of a taxing master. On such a taxation, if the evidence goes to show that, in the opinion of persons in the same profession as the arbitrator, that his charges are fair and reasonable, the taxing master must allow them. In *Mason* v. *Lovatt* (1907, 23 T. L. R. 486) a quantity surveyor was allowed to charge 527*l.* 10*s.* for a reference which lasted 22 days, the arbitrator subsequently taking 13 days to consider his opinion. In *Llandrindod Wells Water Co.* v. *Hawksley* (1904, 20 T. L. R. 241) the fees of an umpire and two arbitrators all being engineers were allowed at 476*l.* 12*s.*, in respect of a reference which lasted 2 days. The arbitrator should state how his fees are made up.

(vii.) **Stating a Case for the Opinion of the Court.**—Where a specific question is referred to an arbitrator, and he decides it, the fact that his decision is erroneous in point of law does not make the award bad on its face so as to admit of its being set aside (*In re King and Duveen* (1913) 2 K. B. 32); nor will the mere fact that the dispute involves questions of law induce the Court to stay a reference to arbitration (*Rowe* v. *Crossley* (1913) 108 L. T. 11). But where a point of law arises during a reference, the arbitrator, if he does not care to decide it, may state a case for the opinion of the Court (Arbitration Act, 1889, s. 19), or the Court may compel him to state a case (*ib.*). He can also make his award in the form of a special case, leaving it to the Court to decide how the judgment shall be entered. Refusal to state a case may constitute misconduct on the part of an arbitrator (*Czarnikow* v. *Roth Schmidt & Co.* (1922) 38 T. L. R. 595).

(viii.) **Costs of a Reference.**—The question of costs should be carefully considered, as the expenses of a reference are often wholly out of proportion to the sum in dispute. In litigation the general rule is 'costs follow the event'—an application of the maxim *vœ victis.* Unless the submission contains some special term as to costs, the arbitrator has full power to decide who is to pay them. He may award costs to be taxed 'as between solicitor and client'—which means that the successful party is nearly indemnified—or he may award costs to be taxed as between litigants in the ordinary way. He may also, in his discretion, award a fixed sum for costs (Arbitration Act, 1889, Schedule I. (i)), or he may declare that each party shall pay his own costs. In deciding whether to make a defendant pay costs, the arbitrator should (it is submitted) consider the nature of any offer made before the proceedings were commenced. Thus supposing a contractor claimed 5,000*l.* and the building owner made a firm offer of 4,000*l.* which was refused. After hearing the evidence, the arbitrator awards 4,000*l.* or less. In such a case he would be justified in disallowing the contractor any costs. An arbitrator can only make a successful plaintiff pay costs in exceptional circumstances as when (e.g.) it appears that although successful he should not have prosecuted his claim. It was held, however, in a case arising under the Small Holdings Act, 1908, the arbitrator in the exercise of his powers under that Act had wider powers in the matter of costs than a High Court judge (*Gray* v. *Baron Ashburton*, 115 L. T. R. 729).

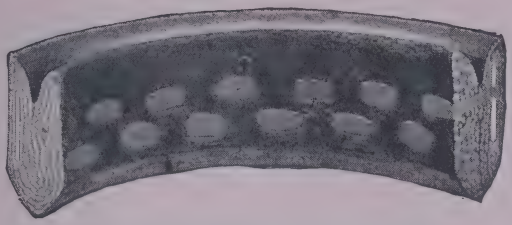
(11) NOTES ON SALE AND PURCHASE OF MACHINERY.

The question which most frequently arises on the sale of machinery, motor cars, etc., is what is the warranty of fitness? Sometimes, of course, there is an express written warranty, but in the absence of that the matter is regulated by section 14 of the Sale of Goods Act, 1893, which provides (in effect) that there is no implied warranty or condition as to the quality or fitness for any particular purpose of goods supplied under a contract of sale, except (1) where the buyer expressly makes known the purpose for which the goods are required so as to show that the buyer relies on the seller's skill or judgment and the goods are of a description which it is in the

course of the seller's business to supply (whether he be the manufacturer or not) there is an implied condition that the goods shall be reasonably fit for such purpose; provided that in the case of the sale of a specified article under its patent or other trade name, there is no implied condition as to its fitness for any particular purpose; (2) where the goods are bought by description from a seller who deals in goods of that description (whether he be the manufacturer or not) there is an implied condition that the goods shall be of merchantable quality; provided that if the buyer has examined the goods there shall be no implied condition as regards defects which such examination ought to have revealed; (3) an implied warranty or condition as to quality or fitness for a particular purpose may be annexed by the usage of trade; (4) an express warranty or condition does not negative a warranty or condition implied by the Sale of Goods Act unless inconsistent therewith. The result of these provisions is that in certain cases the vendor is made liable for latent defects, that is to say, for defects which would not be discoverable on an ordinary examination of the article. Sometimes a contract for the sale of machinery contains provisions for payment of the price by instalments after production of the certificate of the engineer that such instalments are due and payable. It was held in a Scotch case (*Howden* v. *Powell Duffryn Steam Coal Co.* (1912), S. C. 920, Ct. of Sess.) that where, in such circumstances, part of the machinery was rejected, but the manufacturers refused to accept the rejection, the production of the engineer's certificate was not a condition precedent to the right to recover payment.

In the case of an engine which is attached to the freehold, a question may arise, on a sale, as to when the property passes. In *Underwood Ltd.* v. *Burgh Castle Brick and Cement Syndicate* (1922, 1 K. B. 343), a horizontal condensing engine was sold at a price free on rail, London. It was bolted to and embedded in a flooring of concrete. Before it could be delivered on rail it had to be detached and dismantled. The sellers detached it, but in loading it on a truck they damaged it by accident so that the buyers refused to accept it. In an action by the sellers for goods bargained and sold it was held that the property in the engine had not passed to the buyers, inasmuch as the sellers had failed to do something necessary to put it in a deliverable state. Consequently the loss fell on the sellers and not on the buyers.

WALKER'S TRADE MARK LION PACKING



EXPANDING TYPE FOR STEAM.

THE KING OF PACKINGS

There is no Packing that will give—less Trouble, More Durability, and Greater Satisfaction.

WALKER'S LION PACKING TRADE MARK

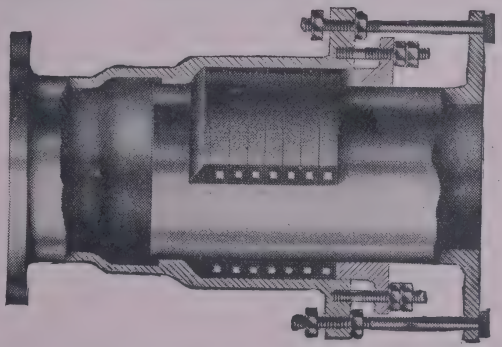
PATENT
'FLEXMET' PACKING

As its name implies, this is an exceedingly Flexible, Semi-Metallic Packing. It has a continuous anti-friction metal wearing face.

Suitable for Shallow Stuffing Boxes and Rotary Engines.

'EMERALD' EXPANSION GLAND PACKING

RESILIENT



DURABLE

A positive cure for one of the most troublesome joints with which Engineers have to contend.

JAMES WALKER & CO. LTD.

LION WORKS, GARFORD STREET,
WEST INDIA DOCK RD., LONDON, E.14

Telephone : East 4253 (3 lines). Telegrams : 'Lioncelle, Pop, London.'

(*To face end of Index p.* 2806)

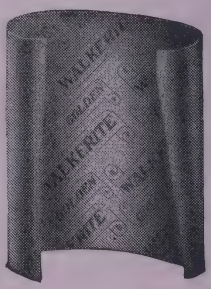
WALKER'S TRADE MARK LION PACKING

'GOLDEN WALKERITE'

COMPRESSED ASBESTOS FIBRE JOINTING

Has proved by Practical Experience to be the Best Jointing on the Market.

SUITABLE FOR STEAM, WATER, PETROL, ACID, AMMONIA, OIL, ETC.



SUPPLIED IN SHEETS, 36″×60″ 40″×40″ 48″×48″ 54″×63″ from $\frac{1}{64}$″ thick.

JOINTS CUT TO ANY SHAPE OR SIZE.

GENUINE BRITISH MANUFACTURE

SOLE MANUFACTURERS:—

JAMES WALKER & CO. LTD.

Lion Works, Garford Street, West India Docks, LONDON, E. 14

FOR CLASSIFIED DIRECTORY OF ADVERTISERS' SPECIALITIES, ALSO GLOSSARIES OF FRENCH, ITALIAN, SPANISH, & RUSSIAN TRADE TERMS, SEE PP. 2821 &C.

'THE ENGINEER'S YEAR-BOOK' CLASSIFIED DIRECTORY OF LEADING ENGINEERING AND ALLIED FIRMS ADVERTISING IN THE 1925 EDITION.

A RELIABLE GUIDE FOR THE USE OF BUYERS OF ENGINEERING MATERIALS, MACHINERY, TOOLS, PLANT, APPLIANCES, ETC.

For Advertisers' Addresses, and Positions of their Announcements in the 'Year-Book,' consult foregoing Alphabetical List, pages 2807 to 2820.

The aim of the Proprietors of 'The Engineer's Year-Book' is to include in this publication only the most reputable firms' announcements, so that readers desiring to order, or specify, the various specialities advertised, may do so with confidence.

***** French, Italian, Spanish, and Russian translations of the terms used in this Directory are given on pages 2889 to 2974.**

RÉPERTOIRE ANALYTIQUE DES ANNONCEURS POUR 1925.

Guide pratique des acheteurs de matériaux pour constructions mécaniques, de machines, d'outils, outillages, appareils, etc.

Les propriétaires de 'The Engineer's Year-Book' (L'Annuaire de l'Ingénieur) se sont efforcés de ne faire figurer dans la présente publication que les annonces des maisons les mieux réputées ; les lecteurs désireux de commander ou de spécifier les différentes spécialités annoncées peuvent donc le faire en toute confiance.

On trouvera pages 2889–2908 la liste des équivalents de ces termes en Français.

Pour les adresses des Annonceurs et les renvois à leurs annonces dans l'Annuaire, voir l'Index alphabétique ci-dessus, pages 2807–2820.

GUIDA CLASSIFICATA DELLE DITTE DI MAGGIOR IMPORTANZA CHE HANNO DEGLI ANNUNCI NELL' EDIZIONE DEL 1925.

Ai compratori di materiale per la meccanica, e di macchinario in genere, questa Guida è assai utile.

I proprietari della 'Engineer's Year-Book' (l' Annuario dell' Ingegnere) si sono limitati a pubblicare in questa guida solo i nomi delle case più rinomate ; i lettori che desiderano ordinare o specificare specialità comprese in questi annunci lo possono quindi fare con tutta sicurezza.

A pagine 2909–2928 trovasi la traduzione in italiano dei termini usati in questo elenco.

Per gli indirizzi delle ditte aventi degli annunci ed il posto dove detti annunci appaiono nella guida vedesi l' elenco alfabetico a pagine 2807–2820.

GUÍA CLASIFICADA DE ANUNCIADORES PARA 1925

Esta Guía es muy conveniente para los compradores de materiales de ingeniería, maquinaria, herramientas, instalaciones, utensilios, etc.

La aspiración de los propietarios de 'The Engineer's Year-Book' ('El Anuario del Ingeniero') es incluir en esta publicación solamente los anuncios de las casas de la mejor reputación ; así es que los lectores que deseen pedir ó especificar cualquiera de los diversos artículos anunciados pueden hacerlo así con confianza.

Una traducción de los términos equivalentes en Castellano se hallará en la lista, páginas 2929–2949.

Para señas de anunciadores y referencias á sus anuncios, consúltese la precedente Lista alfabética, paginas 2807–2820.

ПОДРОБНЫЙ УКАЗАТЕЛЬ СПЕЦІАЛЬНОСТЕЙ АНОНСОДАТЕЛЕЙ 1925 г.

Удобное Руководство для Покупателей Инженерныхъ матеріаловъ, инструментовъ, машинъ, приспособленій, принадлежностей и пр. и пр.

Редакція 'The Engineer's Year-Book' (Инженерный Ежегодникъ) въ настоящемъ изданіи включила объявленія лишь первоклассныхъ фирмъ, такъ что читатель можетъ съ полной увѣренностью снестись съ любой изъ этихъ фирмъ или помѣстить свои заказы на любыя изъ указанныхъ спеціальностей.

Переводъ терминовъ данъ также на Французскомъ и Италіянскомъ и Испанскомъ и Русскомъ языкахъ—см. стр. 2951–2974.

Адреса фирмъ и свѣдѣнія объ ихъ спеціальностяхъ въ 'The Engineer's Year-Book' (Инженерный Ежегодникъ)—см. предыдущій алфавитный списокъ—стр. 2807–2820.

FRANÇAIS.	ANGLAIS.
Démarreurs à liquide et combinateurs	Liquid Starters and Controllers
Démarreurs hydrauliques à hélice	Propeller Starters (Hydraulic)
Désincrustants pour chaudières	Boiler Discrustants
Dessin et traçage	Drawing, Design, and Tracing
Dessinateur pour ingénieurs	Draughtsman (Engineers')
Dessinateur pour ingénieurs	Engineers' Draughtsman
Destructeurs (Séparateurs magnétiques pour)	Destructors (Magnetic Separators for)
Destructeurs de déchets	Destructors (Refuse)
Détrempe	Distemper
Docks flottants	Docks (Floating)
'Duralumin'	'Duralumin'
'Vickers'	'Vickers'
Dynamite	Dynamite
Dynamomètres	Dynamometers
Dynamos et moteurs	Dynamos and Motors
E	
Eau d'alimentation des chaudières (Élimination de l'huile de l')	Boiler Feed-Water, Oil Elimination from
Ébonite	Ebonite
Éclairage des trains	Lighting (Train)
Éclairage des usines	Factories (Lighting of)
Éclairage et chauffage (Installations de gaz acétylène pour)	Lighting and Heating (Acetylene Gas Plants for)
Écoles et collèges de mécanique	Schools and Colleges (Engineering)
Économiseurs de combustible	Fuel Economisers. *See* Economisers
Écrous	Nuts
Électriques (Instruments et appareils)	Electrical Instruments and Apparatus. *See* Instruments and Apparatus (Electrical)
Électro-aimants de levage	Lifting Magnets
Électrodes (pour la soudure à l'arc électrique)	Electrodes (for Electric Arc Welding)
Éléments et batteries d'accumulateurs électriques. *Voir* Accumulateurs électriques	Electrical Storage Cells and Batteries. *See* Storage Cells
Élévateurs. *Voir* Levage et halage	Elevators. *See* Lifting and Hoisting
Éliminateurs d'huile	Oil Eliminators
Émaux, couleurs et vernis	Enamels, Colours, and Varnishes
Embrayages	Clutches
Embrayages à frottement	Friction Clutches
Enduits imperméabilisants	Waterproofing Compounds
Enduits pour parties brillantes	Bright Part Coatings
Enduits pour parties brillantes et apprêts pour machines	Coatings (Bright Part) and Machinery Finishes
'Endural' Câbles électriques	'Endural' Electric Cables
Engrenages	Gearing
Engrenages à vis sans fin	Worm Gearing
Engrenages, arbres de transmission, etc., pour usines. *Voir* Arbres de transmission et engrenages	Mill Gearing, Shafting, etc. *See* Shafting and Gearing
Engrenages cylindriques et coniques	Spur and Bevel Gearing
Engrenages de réduction	Reduction Gears
Engrenages de turbines. *Voir* Turbines à engrenages	Turbine Gears. *See* Geared Turbines
Engrenages en cuir vert	Gears (Raw Hide)
Engrenages hélicoïdaux	Helical Gearing
Engrenages (hydrauliques, à bain d'huile)	Gears (Hydraulic Oil)
Enregistreurs à eau	Water Recorders

Pour les noms des fabricants des spécialités ci-dessus, se reporter aux rubriques correspondantes en anglais dans le 'Classified Directory and Buyers' Guide' ('Répertoire Analytique des Annonceurs'), pages 2821–2888.

FRANÇAIS.	ANGLAIS.
Enregistreurs d'acide carbonique	CO_2 Recorders
Enregistreurs de dépenses et de temps	Costs and Time Recorders
Enregistreurs de rendements de machines	Machine Output Recorders
Enregistreurs de vitesse	Recorders (Speed)
Enseignement mécanique. *Voir* Collèges	Engineering Training. *See* Colleges
Enseignement technique. *Voir* Écoles et Collèges	Technical Training. *See* Schools and Colleges
Entrepreneurs	Contractors
Entrepreneurs d'éclairage électrique	Electric Lighting Contractors
Entrepreneurs de cloisons et constructions incombustibles	Partition Contractors and Fireproof Builders
Entrepreneurs de toitures	Roofing Contractors
Équerres	Squares
Équipements téléphoniques	Telephone Equipment
Escaliers incombustibles	Staircases (Fire-Resisting)
Essais électriques (Instruments d'). *Voir* Instruments	Testing Instruments (Electrical). *See* Instruments
Essieux (Chemins de fer)	Axles (Railway)
Étampages	Stampings
Etoffes à friction 'CHEKKO'	'CHEKKO' Friction Fabrics
Étuves de séchage	Drying Stoves
Évaporateurs à effet multiple	Multiple Effect Evaporators
Évaporateurs à vide pour liquides chimiques	Vacuum Evaporators for Chemical Liquids
Évaporateurs, condenseurs, Appareils pour la distillation de l'eau, etc.	Evaporators, Condensers, Water Distilling Apparatus, etc.
Évaporateurs pour l'industrie sucrière et des liqueurs	Evaporators for Sugar and Trade Liquors

FRANÇAIS.	ANGLAIS.
Excavateurs et transporteurs	Excavators and Transporters
Explosifs	Explosives
Explosifs pour mines	Mining Explosives
Extinction d'incendies (Installations automatiques d')	Sprinklers (Automatic)
Extracteurs de goudron	Tar Extractors
Extracteurs de pieux	Pile Extractors
F	
Fabricants de caoutchouc, gutta-percha et bitume	India Rubber, Gutta Percha, and Bitumen Manufacturers
Fabricants de chaudières	Boiler Manufacturers
Fabricants de fils isolés	Wire (Insulated) Manufacturers
Fabricants de fils métalliques	Wire Manufacturers
Fabricants d'outils de forage de puits artésiens	Boring Tool Makers (Artesian)
Fabricants d'outils, machinistes, etc.	Tool Makers, Machinists, etc.
Fabricants et marchands d'acier	Steel Manufacturers and Merchants
Fabricants et marchands de fer et d'acier	Iron and Steel Manufacturers and Merchants
Fer et acier galvanisés, Fabricants de	Galvanised Iron and Steel Manufacturers
Fer non magnétique	Non-magnetic Iron
Fers et aciers pour constructions	Structural Iron and Steel Work
Feuilles et tuyaux en ciment d'amiante 'Everite'	'Everite' Asbestos Cement Sheets and Pipes
Feuilles et tuiles d'amiante marque 'Poilite'	'Poilite' Asbestos Sheets and Roofing Tiles
Feuilles 'Rok' pour toitures	'Rok' roofing
Feutre et toitures de feutre	Felt and Felt Roofs
Feutres pour fabricants de papier	Paper Makers' Felts

Pour les noms des fabricants des specialités ci-dessus, se reporter aux rubriques correspondantes en anglais dans le 'Classified Directory and Buyers' Guide' ('Répertoire Analytique des Annonceurs'), pages 2821-2888.

FRANÇAIS.	ANGLAIS.
Feutres pour imprimeries, papeteries et imprimeries sur étoffes	Felts for Printing Machinery, Paper Making, and Calico Printing Machinery
Feutres pour toitures	Roofing Felts
Feux et outillage de forges	Smiths' Hearths and Plant
Fibre vulcanisée	Fibre (Vulcanised)
'Fibrent,' tôles d'amiante cimentée plates et ondulées	'Fibrent' Asbestos Cement Corrugated and Flat Sheets
Filets pare-torpilles	Torpedo Defence Nets
Fils métalliques pour clôtures	Fencing Wire
Fil 'Rylax' pour soudure autogène	Welding Wire ('Rylax')
Fils télégraphiques	Telegraph Wire. *See* Wire
Filtres d'air	Air Filters
Filtres d'eau d'alimentation de chaudières. *Voir* Eau d'alimentation	Boiler Feed Filters. *See* Feed Water
Filtres d'huile	Oil Filters
Fonceurs de puits	Shaft Sinkers
Fondeurs	Founders
Fondeurs de cuivre	Brass Founders
Fonte coulée	Cast Iron
Fonte en gueuses	Pig Iron
Forges portatives	Forges (Portable)
Fourneaux de forge	Forging Furnaces. *See* Furnaces
Fournitures pour bureaux de dessins	Drawing Office Requisites
Fournitures pour constructions mécaniques et chemins de fer. *Voir* Matériel de chemins de fer et de tramways	Engineering and Railway Supplies. *See* Railway and Tramway Plant
Fours à creusets	Crucible Furnaces
Fours à gaz	Gas Furnaces. *See* Furnaces
Fours à recuire et à adoucir	Annealing and Tempering Furnaces
Fours chauffés au gaz et au pétrole et fours industriels	Furnaces (Gas and Oil Heated and Industrial)
Fours électriques	Furnaces (Electric)
Fours et matériels industriels à gaz	Industrial Gas Furnaces and Plants
Fours métalliques exempts de fer	Furnaces (Non-ferrous Metal)
Foyers à houille	Coal Furnaces. *See* Furnaces
Foyers de chaudières	Boiler Furnaces
Foyers de chaudières. *Voir* Accessoires de machines et de chaudières	Furnaces (Boiler). *See* Engine and Boiler Fittings
Foyers de chaudières, tubes, etc.	Boiler Furnaces, Tubes, etc.
Fraises	Milling Cutters
Freins de chemins de fer	Brakes (Railway)
Freins dynamométriques	Brakes (Dynamometers)
Freins (Electro-Mécaniques)	Brakes (Electro-Mechanical)
Fumifuges et générateurs de vapeur	Smoke Preventers and Steam Generators
G	
Galvanisateurs	Galvanisers
Garde-fous pour machines	Machinery Guards
Garniture 'Lascar'	Packing ('Lascar')
Garniture d'amiante 'Lascar'	Asbestos Packing ('Lascar')
Garniture 'Lion'	'Lion' Packing
Garniture d'amiante (marque 'Lion')	Asbestos Packing ('Lion')
Garniture marque 'United States'	Packing ('United States')
Garniture 'Pilot'	Packing ('Pilot')
Garniture pour surchauffeurs de locomotives	Locomotive Superheated Packing
Garnitures d'embrayages	Clutch Linings
Garnitures de chaudières. *Voir aussi* Accessoires de machines et chaudières	Boiler Mountings. *See also* Engine and Boiler Fittings
Garnitures de freins et d'embrayages	Brake and Clutch Linings

FRANÇAIS.	ANGLAIS.
Garnitures de joints	Jointing Materials
Garnitures de pistons	Piston Packing
Garnitures hydrauliques	Hydraulic Packings
Garnitures métalliques. *Voir* Bourrages pour machines	Metallic Packing. *See* Engine Packing
Garniture métallique ('Silvertown') pour tiges de pistons	Metallic Piston Rod Packing ('Silvertown')
Garnitures pour machines à vapeur	Steam Packing
Gaze métallique	Wire Gauze
Gazogènes	Gas Producers
Génératrices électriques. *Voir* Dynamos et Moteurs	Generators (Electric). *See* Dynamos and Motors
Goupilles coniques	Taper Pins
Graisse (pour graisseurs)	Grease (Lubricating)
Graisseurs et graisses	Lubricators and Lubricants
Graphite	Graphite
Graphite 'Foliac' Antiencrustante pour Chaudières	'Foliac' Boiler Graphite
Graveurs, dessinateurs et imprimeurs	Engravers, Draughtsmen, and Printers
Gréement pour Aéroplanes et Ballons Dirigeables	Rigging for Aircraft
Grues. *Voir* Appareils de levage	Cranes. *See* Lifting and Hoisting Machinery
Grues à main. *Voir* Appareils de levage	Hand Cranes. *See* Lifting and Hoisting Machinery
Grues preneuses (électriques)	Grabbing Cranes (Electric)
Gyroscopes	Gyroscopes
H	
Haussières (en acier galvanisé)	Hawsers (Galvanized Steel Wire)
Hélices	Propellers, Screw Propellers
Horloges électriques	Clocks, Electric. *See* Electric Clocks
Horloges enregistreuses	Time Recorders
Houillières (câbles d'acier pour)	Collieries (Steel Wire Ropes for)
Houillières (équipement électrique pour)	Collieries (Electrical Equipment of)
Huile pour filetage	Screwing Oil
Huiles, composés lubrifiants, etc.	Oils, Lubricating Compounds, etc.
Hydrofuge et revêtement au bitume	Damp Course and Bitumen Sheeting
Hydrofuge et revêtement 'Callendrite'	'Callendrite' Dampcourse and Sheeting
I	
Imperméabilisation des réservoirs	Reservoirs (Waterproofing of)
Imprimeurs, lithographes, dessinateurs et graveurs	Printers, Lithographers, Draughtsmen, and Engravers
Incendies (Installations automatiques d'extinction d')	'Grinnell' Sprinklers
Indicateurs d'effort (de tension)	Strainmeters
Indicateurs d'élongation	Extensometers
Indicateurs de niveau d'eau	Water Level Indicators
Indicateurs de signaux de mines	Mine Signal Indicators
Indicateurs de tirage	Draught Gauges
Indicateurs de vide	Vacuum Gauges
Indicateurs de vitesse marins	Marine Speed Indicator
Indicateurs pour machines à vapeur	Indicators (Steam Engine)
Ingénieurs (Aéronautiques). Voir Aéronautiques (Ingénieurs)	Engineers (Aeronautical). See Aeronautical Engineers
Ingénieurs-Conseils	Advisory Engineers
Ingénieurs des mines	Mining Engineers
Ingénieurs électriciens	Electrical Engineers
Ingénieurs pour économie du combustible	Engineers (Fuel Economy)

Pour les noms des fabricants des spécialités ci-dessus, se reporter aux rubriques correspondantes en anglais dans le 'Classified Directory and Buyers' Guide' ('Répertoire Analytique des Annonceurs'), pages 2821–2888.

Lampes à l'arc	Arc Lamps
Lampes à filaments métalliques	Metal Filament Lamps
Lampes de sûreté de mineurs	Miners' SafetyLamps
Lampes électriques	Lamps (Electric)
Lampes industrielles	Lamps (Industrial)
Lampes : Torches pour soutes et pour mécaniciens en général	Lamps ; Torch, Bunker, etc., for Engineers generally
Levage et montage	Lifting and Hoisting
Lignes de telphérage	Telphers
Livres et journaux scientifiques	Books and Journals, Scientific
Locomotives	Locomotives
Locomotives à pétrole (combustion interne)	Oil Locomotives (Internal Combustion)
Logements de chaudières	Settings (Boiler)
Logements de chaudières (perfectionnés)	Boiler Settings (Improved)
Logements de chaudières de Lancashire (perfectionnés)	Lancashire Boiler Settings (Improved)
Logements de cornues	Settings (Retort)
Lubrifiants pour moteurs	Motor Lubricants
M	
Machines automatiques, Fabricants de	Automatic Machine Makers
Machines à aléser et à dresser	Boring and Facing Machines
Machines à blanchir, teindre et apprêter	Bleaching, Dyeing, and Finishing Machinery
Machines à broyer, élever et transporter le charbon	Coal Grinding, Elevating and Conveying Machinery
Machines à broyer et à pulvériser	Crushing and Pulverising Machinery
Machines à calculer	Counting Instruments
Machines à cintrer les tuyaux	Pipe-Bending Machines
Machines à ciment	Cement Machinery
Machines à cisailler, poinçonner et cintrer	Shearing, Punching, and Bending Machines
Machines à électro-aimants	Machinery (Electro-Magnets)
Machines à essayer le ciment	Cement Testing Machines
Machines à essayer le ciment de Portland	Testing Machines for Portland Cement
Machines à fabriquer le papier et la pâte à papier	Paper and Pulp Making Machinery
Machines à fabriquer les cartouches	Cartridge Machinery
Machines à faire la glace. *Voir* Machines réfrigérantes	Ice-making Machinery. *See* Refrigerating Machinery
Machines à fileter	Screwing Machines
Machines à fraiser	Milling Machines
Machines à laver le charbon	Coal-washing Machinery
Machines à moudre	Grinding Machinery
Machines à nettoyer les grains et semences	Grain and Seed Cleaning Machinery
Machines à peindre	Painting Machines
Machines à poinçonner, cisailler et cintrer	Punching, Shearing, and Bending Machines
Machines à polir	Polishing Machinery
Machines à poser les câbles	Cable-laying Machinery
Machines à raboter, mortaiser, fileter et étaux-limeurs	Planing, Slotting Screwing, and Shaping Machines
Machines à réduire en pulpe	Pulp-making Machinery
Machines à souder	Soldering Machines
Machines à souder les résistances	Resistance Welding Machines
Machines à tailler les engrenages à la vis-fraise	Gear Hobbing Machines
Machines à travailler le bois	Wood-working Machinery

Pour les noms des fabricants des spécialités ci-dessus, se reporter aux rubriques correspondantes en anglais dans le 'Classified Directory and Buyers' Guide' ('Répertoire Analytique des Annonceurs'), pages 2821-2888.

Raccords pour tuyaux flexibles	Hose Couplings
Rails en acier et accessoires	Steel Rails and Accessories
Rails et accessoires de fixation	Rails and Fastenings
Ramasse (Métaux de)	Scrap Metals

Pour les noms des fabricants des specialités ci-dessus, se reporter aux rubriques correspondantes en anglais dans le 'Classified Directory and Buyers' Guide' ('Répertoire Analytique des Annonceurs'), pages 2821–2888.

FRANÇAIS.	ANGLAIS.
Rampes de chemins de fer	Railway Ramps
Ranchers en acier	Stanchions (Steel)
Réchauffeurs et échauffeurs intermédiaires	Interheaters and Reheaters
Réchauffeurs, filtres et purificateurs d'eau d'alimentation	Feed-Water Heaters, Filters and Purifiers
Recuisage	Annealing
Recuit. *Voir* Fours à recuire	Tempering Furnaces. *See* Furnaces
Refroidisseurs d'huile	Oil Coolers
Règles à calculer. *Voir* Instruments scientifiques etc.	Slide Rules. *See* Instruments, Mathematical, etc.
Règles en acier	Steel Rules
Régulateurs automatiques	Regulators (Automatic)
Régulateurs d'eau d'alimentation	Water Regulators (Feed)
Régulateurs de pompes	Pump Governors
Régulateurs de température	Temperature Regulators
Régulateurs pour machines à vapeur	Governors (Steam Engine)
Réparations de navires et de machines	Ship and Engine Repairers
Réparation des chaudières (Soudure à l'arc électrique pour la)	Boiler Repairs (Electric Arc Welding for)
Réservoirs en fonte	Cast Iron Tanks
Réservoirs et citernes	Tanks and Cisterns
Ressorts	Springs
Revêtement hydrofuge au bitume	Bitumen Damp-proof Sheeting
Revêtements en coton silicaté et en laine de scorie	Silicate Cotton and Slag Wool Coverings
Revêtements pour chaudières etc.	Coverings for Boilers, etc.
Revêtements pour chaudières et tuyaux	Boiler and Pipe Coverings
Revêtements pour murs et plafonds	Wall and Ceiling Sheets
Revêtements pour tuyaux	Pipe Coverings
Riblons de fer et d'acier	Iron and Steel Scrap
Rivets en fer, acier, cuivre, bronze de marine, etc.	Rivets (Iron, Steel, Copper, Naval Brass, etc.)
Riveuses électriques	Riveters (Electric)
Riveuses hydrauliques et pneumatiques	Riveters (Hydraulic and Pneumatic)
Robinets en cuivre pour eau, vapeur et gaz	Cocks (Brass) for Water, Steam, and Gas
Rodeurs de sièges de soupapes	Valve Reseaters
Rondelles pour verres d'indicateurs de niveau	Gauge Glass Washers
'Rosseline' (pour moteurs à gaz et à pétrole)	'Rosseline' (for Gas and Oil Engines)
Roues à empreintes pour chaînes	Chain Wheels
Roues d'engrenage	Wheel Gearing
Roues, moteurs et turbines hydrauliques	Water Wheels, Water Motors, and Turbines
Roues Pelton	Pelton Wheels

S

Sabots de freins	Brake Blocks
Salaires (Calculateurs de)	Wages Calculators
Scies à couper les métaux et machines	Hack Saws and Machines
Scies pour bois et métaux	Saws for Wood and Metal Cutting
Sécheurs et épurateurs de vapeur	Steam Dryers and Purifiers
Sections refoulées brevetées en laiton, bronze, etc.	Sections (Patent Extruded), Brass, Bronze, etc.
Segments de pistons	Piston Rings
Segments de pistons 'S.E.A.'	'S.E.A.' Ring
Séparateurs d'eau de condensation	Steam Separators
Séparateurs de graisse	Grease Separators

Pour les noms des fabricants des specialités ci-dessus, se reporter aux rubriques correspondantes en anglais dans le 'Classified Directory and Buyers' Guide' ('Répertoire Analytique des Annonceurs'), pages 2821-2888.

FRANÇAIS.	ANGLAIS.
Séparateurs de suie	Soot Removers
Séparateurs électro-magnétiques	Separators(Magnetic)
Séparateurs magnétiques	Magnetic Separators
Séparation de l'huile de l'eau de condensation	Separation of Oil from Condensed Steam
Serpentins	Pipe Coils
Serrures, verrous, etc.	Locks, Bolts, etc.
Signaux. *Voir* Chemins de fer—Signaux	Signals. *See* Railway Signals
Signaux de chemins de fer et dispositifs de sûreté	Railway Signals and Safety Appliances
Signaux étanches pour mines	Mining Signals (Watertight)
Solives en acier	Joists (Steel)
Sondeuses à diamants	Diamond Drillers
Sonnettes (électrique)	Bells (Electric)
Soudure autogène 'Thermit'	'Thermit' Welding
Soudure à l'arc électrique 'Daysohms'	'Daysohms' Electric Arc Welding
Soudure électrique	Electric Welding
Soudure et découpage de métaux	Welding and Cutting of Metals
Soudure oxy-acétylénique	Oxy-Acetylene Welding
Souffleries. *Voir* Ventilateurs	Blowers. *See* Fans
Souffleurs de carneaux	Flue Blowers
Souffleurs électriques	Electric Blowers
Soupapes automatiques à vapeur	Steam Valves (Automatic)
Soupapes à manchon pour pompes à l'air	Bush Valves for Air Pumps
Soupapes de réduction. *Voir* Soupapes	Reducing Valves. *See* Valves
Soupapes et robinets	Valves and Cocks
Sous-ardoisage	Underslating
Spécialistes pour l'économie de la houille	Coal Economy Specialists
Spécialités de Graphite 'Foliac'	'Foliac' Graphite Specialities
Spécialités pour cémentation	Cementation Specialities
Substances pour conserver le bois	Wood Preservatives
Substances réfractaires	Refractories
Surchauffeurs	Superheaters
Surchauffeurs de locomotives	Locomotive Superheaters
Surchauffeurs marins	Marine Superheaters
Surfaces de frottement	Friction Surfaces
Surfaces de frottement 'Ferodo'	'Ferodo' Friction Surfaces
Systèmes de conducteurs flexibles	Wiring Systems (Flexible)
Systèmes de placement de conducteurs électriques. *Voir* Systèmes de placement de fils électriques flexibles	Electric Wiring Systems. *See* Wiring Systems (Flexible)
Systèmes pour l'économie du combustible	Fuel Economy Systems
T	
Tableaux de distribution des accumulateurs	Battery Switchboards
Tachymètres	Tachometers
Taquets ou sabots de mise en rail (plaques d'accès)	Railway Re-railing Ramps
Tarauds et filières	Taps and Dies
Tarières rubanées ou américaines	Twist Drills
Tartrifuges et anti-rouilles pour chaudières	Scale and Corrosion in Boilers (Preventives of)
Tartrifuges pour chaudières	Boiler Preservatives
Têtes de pieux	Pile Helmets
Thermomètres	Thermometers
Tiges et sections creuses (en laiton, cuivre, etc.)	Hollow Rods and Sections (Brass, Copper, etc.)
Tiges et sections de cuivre	Copper Rods and Sections
Tiroirs	Slide Valves

Pour les noms des fabricants des specialités ci-dessus, se reporter aux rubriques correspondantes en anglais dans le 'Classified Directory and Buyers' Guide' ('*Répertoire Analytique des Annonceurs*'), *pages* 2821–2888.

FRANÇAIS.	ANGLAIS.
Tissus et ouvrages en fils métalliques	Wire Work and Woven Wire
Toiles métalliques galvanisées	Galvanized Wire Netting
Toits, constructions en fer, etc.	Roofs, Iron Buildings, etc.
Toiture 'Ruberoid'	'Ruberoid' Roofing
Tôles à chaudières (acier)	Boiler Plates (Steel)
Tôles d'acier imperforable	Bullet-proof Steel Plates
Tôles de toiture d'amiante cimentées ondulées	Asbestos Cement Corrugated Roofing Sheets
Tôles découpées, enveloppes de cylindres, etc.	Sheet Metal Work, Cylinder Cases, etc.
Tôles plates d'amiante cimentée (pour murailles, cloisons, plafonds, etc.)	Asbestos Cement Flat Sheets (for Walls, Partitions Ceilings, etc.)
Tôles réfractaires pour cloisons et murailles	Fireproof Partition and Wall Sheets
Tournage (tou métal)	Turned Work (any Metal)
Tours. *Voir* Fabricants d'outils	Lathes. *See* Tool Makers
Tours et outils à grande vitesse	'Speedicut' High-Speed Tools
Tours réfrigérantes	Cooling Towers
Tours révolver	Turret Lathes
Tracteurs à vapeur et électriques	Traction Engines (Steam and Electric)
Trains finisseurs	End Mills
Tramways à câble métallique	Tramways (Wire Rope)
Tramways, Câbles aériens en acier pour	Tramways (Steel Wire Ropes for)
Tramways et Chemins de fer électriques. *Voir* Chemins de fer et Tramways électriques	Tramways and Railways (Electrical). *See* Electric Railways and Tramways
Transformateurs (Énergie électrique	Transformers (Electric Power)
Transmissions (hydrauliques, à huile)	Transmission (Hydraulic, Oil)
Transformateurs de marine	Marine Transformers
Transformateurs en cascade	Motor Converters
Transporteurs	Transporters
Transporteurs aériens par câbles	Wire Ropeways
Transporteurs par câbles	Cableways
Transporteurs par câbles aériens	Aerial Ropeways
Trempe de surface	Case Hardening
Treuils (à vapeur, à l'électricité, à l'essence	Winches (Steam, Electric & Petrol)
Treuils (friction)	Winches (Friction)
Treuils roulants	Crab Winches
Trou de sonde (Pompes à puits profonds)	Borehole (Deep Well Pumps)
Tubes	Tubes
Tubes à dépêches pneumatiques etc.	Pneumatic Despatch Tubes etc.
Tubes d'acier. *Voir* Tubes	Steel Tubes. *See* Tubes
Tubes d'acier pour canalisations électriques	Steel Conduits for Electric Wiring
Tubes de chaudières	Boiler Tubes
Tubes de condenseurs (cuivre rouge) *Voir* Tubes de cuivre rouge	Condenser Tubes (Copper). *See* Copper Tubes
Tubes de cuivre rouge	Copper Tubes
Tubes en fer	Iron Tubes. *See* Tubes
Tubes en fer et en acier	Iron and Steel Tubes
Tubes et accessoires	Tubes and Fittings
Tubes et serpentine réfrigérateurs	Refrigerating Tubes and Coils
Tubes et tuyaux hydrauliques	Hydraulic Tubes and Pipes
Tubes métalliques flexibles	Tubing (Flexible Metallic)
Tubes pneumatiques	Tubes (Pneumatic)
Tubulures d'observation pour chaudières	Inspection Blocks for Boilers

Pour les noms des fabricants des spécialités ci-dessus, se reporter aux rubriques correspondantes en anglais dans le 'Classified Directory and Buyers' Guide' ('*Répertoire Analytique des Annonceurs*'), *pages* 2821–2888.

FRANÇAIS.	ANGLAIS.
Tuiles d'amiante	Asbestos Roofing Tiles
Tuiles et tôles ondulées (Ciment-Amiante)	Corrugated Tiles and Sheets (Asbestos-Cement)
Turbines à vapeur	Turbines (Steam). *See* Steam Turbines
Turbines à vapeur et accessoires	Steam Turbines and Fittings
Turbines, roues hydrauliques et moteurs hydrauliques	Turbines, Water Wheels, and Water Motors
Turbo-alternateurs	Turbo Alternators
Turbo - génératrices. *Voir* Dynamos et Moteurs	Turbo - Generators. *See* Dynamos and Motors
Turbo-pompes	Turbo-Pumps
Tuyaux. *Voir* Tubes	Pipes. *See* Tubes
Tuyaux de fonte pour eau et gaz	Cast Iron Pipes for Water and Gas Purposes
Tuyaux de vapeur. *Voir* Tubes	Steam Pipes. *See* Tubes
Tuyaux de ventilation	Ventilating Shafts
Tuyaux et accessoires pour gaz	Gas Tubes and Fittings
Tuyaux flexibles en cuir et en toile etc.	Hose Pipes, Leather and Canvas Hose, etc.
Tuyaux flexibles pour brigades de pompiers, usines, etc.	Hose for Fire Brigades, Mills, etc.
Tuyaux flexibles pour le chauffage à vapeur	Steam Heating Tubes (Flexible)
Tuyaux métalliques flexibles	Hose (Flexible Metallic), Metallic Tubing (Flexible)
Tuyères de haut fourneaux	Blast Furnace Tuyères
U	
Ustensiles et machines agricoles	Agricultural Tools and Machinery
V	
Vannes et robinets-vannes	Sluice Gates and Valves
Vannes pour docks (Constructeurs de)	Dock Gates (Builders of)
Vaporisateurs	Spraying Machines
Véhicules à traction motrice (pour le commerce)	Motor Vehicles (Commercial)
Ventilateurs : soufflants, aspirants, électriques, etc.	Fans : Blowing, Exhaust, Electric, etc.
Ventilateurs électriques. *Voir* Ventilateurs	Electric Fans. *See* Fans
Ventilateurs épurateurs de gaz	Gas Washing Fans
Ventilation, chauffage, etc.	Ventilating, Heating, etc.
Vérins Duff	Duff Jacks
Vérins hydrauliques et à vis	Jacks (Hydraulic and Screw)
Vernis	Varnishes
Vernis et enduits isolants	Insulating Varnishes and Compounds
Verres d'indicateurs de niveau d'eau	Gauge Glasses
Verres pour graisseurs	Lubricating Glasses
Vide (Pompes à). *Voir* Pompes	Vacuum Pumps. *See* Pumps
Vieux métaux	Metal Scrap. *See* Scrap Metals
Vignettes à jour	Stencil Plates
Vis (fer, acier, cuivre et bronze marin)	Screws (Iron, Steel, Copper, and Naval Brass)
Vis mécaniques	Machine Screws
Voitures et wagons de chemins de fer	Carriages and Wagons (Railway)
Voltmètres. *Voir* Instruments électriques	Voltmeters. *See* Instruments (Electrical)
Vulcanite et fibre vulcanisée	Vulcanite and Vulcanised Fibre
W	
Wagons à bascule	Tip Wagons
Wagons de chemins de fer	Wagons (Railway
' Woodite '	' Woodite '
Z	
Zincs non incrustants pour piles	Zincs (Non-encrusting for Primary

Pour les noms des fabricants des spécialités ci-dessus, se reporter aux rubriques correspondantes en anglais dans le ' Classified Directory and Buyers' Guide (' *Repertoire Analytique des Annonceurs* '), *pages* 2821–2888.

TRADUZIONE DELLE RUBRICHE CHE FIGURANO NELLA GUIDA CLASSIFICATA DELLE VARIE SPECIALITÀ COMPRESE NEGLI ANNUNCI (pag. 2821-2888).

Per i nomi dei fabbricanti delle specialità elencate su questa pagina il lettore è pregato di vedere le rubriche corrispondenti in lingua inglese nel 'Classified Directory and Buyers' Guide' ('*Guida classificata degli annunci*'), *pag.* 2821-2888. *Per gli indirizzi delle ditte aventi degli annunci ed il posto dove detti annunci appaiono nella guida vedesi l' elenco alfabetico a pagine* 2807-2820.

ITALIANO.	INGLESE.
A	
Accessori di bronzo	Gunmetal fittings
Accessori per aeroplani	Aeroplane Accessories
Accessori per automobili	Motor Car Accessories
Accessori per caldaie	Boiler Fittings. *See* Engine and Boiler Fittings
Accessori per motrici e caldaie, focolari, tubi, ecc.	Engine and Boiler Fittings, Boiler Furnaces, Tubes. etc.
Acciai a tempera di superficie	Case Hardening Steels
Acciai al cromo-vanadio	Chrome - Vanadium Steels
Acciai al nichelio ed al cromo-nichelio	Nickel and Nickel Chrome Steels
Acciai fusi al crogiuolo	Crucible Cast Steels
Acciai per aviazione	Aircraft Steels
Acciai per stampi	Die Steels
Acciaio a tempera d'aria per ingranaggi	Air Hardening Gear Steel
Acciaio ad alta tensione	High Tensile Steel
Acciaio al manganese	Manganese Steel
Acciaio (lingotti)	Steel (Blooms and Billets)
Acciaio elettrico, Fabbricanti di	Electric Steel Manufacturers
Acciaio immacolato ed irruginibile	Stainless and Rustless Steel
Acciaio in lamiere per piloni	Steel Sheet Piling
Acciaio irruginibile	Rustless Steel
Acciaio irruginibile di Firth	Firth's Stainless Steel
Acciaio lucente. Fabbricanti di	Bright Steel Manufacturers
Acciaio 'Mesmeric' a tempera di superficie	'Mesmeric' Case Hardening Steel
Acciaio per macchine, Fabbricanti di	Machinery Steel Manufacturers
Acciaio per magneti	Magnet Steel
Acciaio per utensili	Tool Steel
Acciaio rapido per utensili	High-Speed Tool Steel
Acciaio rapido 'Speedicut'	'Speedicut' High-speed Steels
Acciaio Siemens - Martin	Siemens - Martin Steel
Accoppiamenti ferroviari	Railway Couplings
Accoppiatori per Tubi flessibili	Hose Couplings
Accumulatori	Accumulators. *See* Batteries
Accumulatori (di elementi e batterie)	Storage Cells and Batteries
Accumulatori elettrici	Storage Cells
Accumulatori idraulici	Accumulators (Hydraulic)
Acetilene	Acetylene
Acetilene, Impianti per generare	Acetylene Generating Plants
Acido idrocloridico	Hydrochloric Acid
Acido nitrico	Nitric Acid

ITALIANO.	INGLESE.	ITALIANO.	INGLESE.
Acido per accumulatori	Accumulator Acid	Apparecchi di Radio-Telegrafia	Radio-Telegraphic Apparatus
Acido solforico	Sulphuric Acid	Apparecchi di ricupero	Recovery Plants
Acqua di alimentazione (misurazione dell')	Feed-Water (Measurement of)	Apparecchi di sollevamento	Lifting and Hoisting
Acqua per alimentazione caldaie (Eliminazione dell'olio dall')	Boiler Feed-Water, Oil elimination from	Apparecchi di sollevamento	Lifting and Hoisting Machinery
Affilatrici di punte	Drill Sharpeners	Apparecchi di trazione	Hauling Plant. *See* Winding and Hauling
Alberi ferroviari a gomito	Railway Crank-shafts	Apparecchi elettrici per il riscaldamento e per la cucina	Electric Heating and Cooking Apparatus
Alesatori per sedi di valvole	Valve Reseaters	Apparecchi e macchine per sollevamento	Lifting and Hoisting Machinery and Lifting Tackle
Alesatoi e maschi	Reamers and Taps	Apparecchi fotografici	Photographic Apparatus
Alluminio (lingotti, fogli, tubi, fili, cavi, sezioni, ecc.)	Aluminium (Ingots, Sheets, Tubes, Wire, Cables, Sections, etc.)	Apparecchi fotografici e otturatori	Cameras and Shutters
Alluminio, Polvere d'	Aluminium Powder	Apparecchi interruttori	Switch Gear
Alternatori	Alternators	Apparecchi per essiccare (Essiccatoi)	Drying Apparatus
Alternatori a turbina	Turbo Alternators	Apparecchi per estinguere incendi	Fire Extinguishing Appliances
Amianto (articoli, guarnizioni, ecc.)	Asbestos Goods, Fittings, etc.	Apparecchi per filtrare	Filtering Apparatus
Amianto (rivestimenti e materassi)	Asbestos Coverings and Mattresses	Apparecchi per forzare i bulloni	Bolt Forcers
Analisi dei gas prodotti dalla combustione nelle caldaie	Boiler Flue Gases (Analysis of)	Apparecchi per galvanizzare	Galvanisers
Anelli per giunti di rame	Copper Jointing Rings	Apparecchi per il raffreddamento ad acqua	Water-Cooling Apparatus
Anelli per tubi di vetro per livelli	Gauge Glass Rings	Apparecchi per il tiraggio forzato per aspirazione e pressione	Forced and Induced Draught Apparatus
Anelli per pistone	Piston Rings	Apparecchi per la distillazione dell'acqua dolce	Distilling Apparatus (Fresh Water)
Anelli per vetri di livello d' acqua	Gauge Glass Washers	Apparecchi per la distillazione dell'acqua ecc. *Vedere anche* Condensatori	Water Distilling Apparatus etc. *See also* Condensers
Anelli 'S.E.A.'	'S.E.A.' Rings	Apparecchi per l'analisi degli olii	Oil Testing Apparatus
Appaltatori	Contractors		
Apparecchi automatici per estinguere incendi, marca 'Grinnell'	'Grinnell' Sprinklers		
Apparecchi automatici per l'alimentazione del fuoco nelle caldaie	Mechanical Stokers		
Apparecchi chimici ed elettro-chimici	Chemical and Electro-Chemical Apparatus

Composiciones no conductoras	Non-conducting Compositions
Composiciones para Resguardar Piezas de Metal Pulimentadas	Bright Part Coatings
Compresores de Aire	Air-Compressors
Compuertas de Esclusa y Válvulas	Sluice Gates and Valves
Compuestos para cortar	Cutting Compounds
Condensadores Cinemáticos 'Contraflo'	'Contraflo' Kinetic Condensers
Condensadores, Evaporadores, Aparatos para Dulcificar y Destilar el Agua, etca.	Condensers, Evaporators, Water Softening and Distilling Apparatus, etc.
Conductos. *Véase* Conductos de Acero y Sistemas de Alambres Eléctricos	Conduits. *See* 'Steel Conduits' and 'Wiring Systems'
Conductos de Acero para Alambres Eléctricos	Steel Conduits for Electric Wiring
Conductos para Descargar Té	Tea Shoots
Conexiones Flexibles	Flexible Couplings
Conos de Fricción	Friction Clutches
Construcciones de Hormigón Armado	Reinforced Concrete Construction
Constructores de Buques	Ship Builders
Constructores de Buques Aljibes para Petróleo	Oil Tank Ships (Builders of)
Constructores de Cajas Hidráulicas y Puertas de Diques	Caissons (Builders of)
Constructores de Diques Flotantes	Floating Dock Builders
Constructores de Puertas de Entrada de Diques	Dock Gates (Builders of)
Constructores y Armadores de Barcazas	Barge Builders and Owners
Contadores de Agua	Meters (Water)
Contadores de Agua Perdida	Waste Water Meters
Contadores de aire	Meters (Air)
Contadores de carbón	Meters (Coal)
Contadores eléctricos	Meters (Electrical)
Contadores de gas	Gas Meters
Contadores para minas	Minemeters
Contratistas	Contractors
Contratistas de Alumbrado Eléctrico	Electric Lighting Contractors
Contratistas de Paredes Divisorias y Constructores de Obras contra Incendios	Partition Contractors and Fireproof Builders
Contratistas de Tejados	Roofing Contractors
Cordones y Cables de Alambre de Acero para Aeroplanos	Aeroplane Steel Wire Strands and Cables
Correaje de Transmisión de Balata	Balata Belting
Correas de Algodón para Transmisión	Cotton Belting
Correas de Cuero. *Véase* Correas de Transmisión	Leather Belting. *See* Belting
Correas de Transmisión de Pelo de Camello, Unicos Fabricantes de la Marca 'Camel'	'Camel' Hair, 'Camel' Brand Belting (Sole Makers of)
Correas de Transmisión, etca., de Cuero, Algodón, Pelo, Caucho, etca.	Belting, etc.—Leather, Cotton, Hair, India Rubber, etc.
Correas y Cuerdas de Transmisión, etca.	Driving Bands, Ropes, etc.
Corte y Soldadura de Metales	Metal Cutting and Welding
Crema para Correas de Transmisión	Belting Cream
Crisoles	Crucibles
Cuadrantes	Dials

Pilas y Baterías de Acumulación Eléctrica. *Véase* Baterías (Acumulación Eléctrica)	Electrical Storage Cells and Batteries. *See* Storage Cells
Pilotes, Armaduras para Clavarlos	Pile Driving Frames
Pilotes (Chapa de Acero)	Piles (Steel Sheet)
Pilotes, Equipos para Clavarlos	Pile Driving Equipments
Piñones de Papel	Paper Pinions
Pintura al Temple	Distemper
Pintura Anticorrosiva	Anti-corrosive Paint
Pintura Silica-Grafito 'Foliac'	'Foliac' Silica-Graphite Paint
Pinturas, Colores, Esmaltes y Barnices	Paints, Colours, Enamels and Varnishes
Pinturas para Conservar Obra de Hierro y Acero	Paints for Preserving Iron and Steel Work
Pirómetros	Pyrometers
Pizarras para techos	Slating
Pizarras y Planchas de Cemento	Cement Slates and Boards
Planchas con marcas de fábrica	Trade Mark Plates
Planchas con nombres para todas las industrias (Grabadas o fundidas)	Name Plates for all Trades (Engraved or Cast)
Planchas con números	Number Plates
Planchas de acero a prueba de balas	Bullet-Proof Steel Plates
Planchas de Acero para Calderas	Boiler Plates (Steel)
Planchas de índice de velocidades	Speed Index Plates
Planchas de instrucciones	Instruction Plates
Planchas para Suelos	Plates (Floor)
Planímetros	Surface Gauges
Plataformas giratorias	Turntables
Poleas	Pulleys
Poleas para Correas y Cuerdas de Transmisión	Belt and Rope Pulleys
Poleas para Cuerdas. *Véase* Poleas para Correas y Cuerdas de Transmisión	Rope Pulleys. *See* Belt and Rope Pulleys
Pólvora para Barrenos	Blasting Powder
Postes de Hierro para Telégrafos	Telegraph Poles (Iron)
Pozos de Petróleo (Cuerdas para)	Oil Well Ropes
Prensas con Fuerza Motriz	Power Presses
Prensas de Aceite	Oil Presses
Prensas de Cimbrar	Bending Presses
Prensas de Forjar	Forging Presses
Prensas para Desperdicios de Metales	Scrap Presses
Prensas para Hacer Bombas	Shell Presses
Prensas para Llantas	Tyre Presses
Preparaciones para última Mano á las Máquinas	Machinery Finishes
Preservativos (Calderas)	Preservatives (Boiler)
Preservativos de Calderas	Boiler Preservatives
Preservativos (Madera)	Preservatives (Wood)
Preservativos de la Madera	Wood Preservatives
Preventivos del Moho	Rust Preventives
Productores de Gas	Gas Producers
Productos Químicos	Chemicals
Propietarios de Diques	Dock Owners
Propietarios de Diques de Carena	Dry Dock Owners, Graving Dock Owners
Propulsión Electrica de Buques	Electric Ship Propulsion
Propulsores	Propellers
Protectores de Indicadores de Cristal	Gauge Glass Protectors
Provisión de Ingeniería y Material de Ferrocarriles. *Véase* Establecimiento de Ferrocarriles y Tranvías	Engineering and Railway Supplies. *See* Railway and Tramway Plant
Publicaciones Técnicas. *Véase* Libros y Periódicos	Publications (Technical). *See* Books and Journals
Puentes Colgantes de Cables de Alambre	Bridges (Wire Rope Suspension)
Puentes, Vigas, etca.	Bridges, Girders, etc.
Puertas Abatibles	Collapsible Gates

Para hallar los nombres de los fabricantes de los artículos especiales antes mencionados, refiéranse á los títulos equivalentes en inglés en la Classified Directory and Buyers' Guide ('Guía Clasificada de Anuncios'), páginas 2821–2888.

Вагоны (Жел. Дор.)	Wagons (Railway)	Воздухомѣры	Air Meters
Вагоны (Пассажирскіе и Товарные)	Carriages and Wagons (Railway)	Водоизмѣрители и пр.—см. Паровые манометры	Water Gauges, etc. (see 'Steam Gauges')
Вагранки	Cupolas	Водолазные аппараты	Diving Apparatus
Вакуумные и Паровые отводчики	Vacuum and Steam Traps	Водомѣрныя стекла	Gauge Glasses
Вакуумныя чашки (концентраціонныя)	Vacuum Pans (Concentrating)	Водомѣры	Water Meters
Вакуумъ-испарители для химическихъ жидкостей	Vacuum Evaporators for Chemical Liquids	Водонапорныя башни	Water Towers
Вакуумъ-насосы—см. Насосы	Vacuum Pumps (see 'Pumps')	Водонепроницаемые составы	Waterproofing Compounds
Валы и приводы	Shafting and Gearing	Водонепроницаемые составы для зданій	Buildings (Waterproofing of)
Вентиляторы: воздуходувные, выпускные, электрическіе и пр.	Fans (Blowing, Exhaust, Electric, etc.)	Водоохладители	Water-cooling Apparatus
Вентиляціонные валы	Ventilating Shafts	Водо региструющіе аппараты	Water Recorders
Вентиляціонные техники	Ventilating Engineers	Водотрубные котлы—см. Котельные Заводчики	Water-tube Boilers (see 'Boiler Manufacturers')
Вентиляція, Отопленіе и пр.	Ventilating, Heating, etc.	Водяныя колеса, Водяные двигатели и Турбины	Water Wheels, Water Motors and Turbines
Веревочныя подвѣски для летательныхъ машинъ	Rigging for Air Craft	Водяныя краски	Distemper
Вертикальные сверлильные станки	Vertical Drilling Machines	Воздуходувки для камина	Flue Blowers
Вещества, предохраняющія отъ ржавчины	Rust Preventives	Воздухолетательныхъ машинъ, фабр. (см. Аэроплановъ, строители)	Aircraft Manufacturers (see Aeroplane Builders)
Взрывающій порохъ	Blasting Powder	Воздушные компрессоры	Air-Compressors
Взрывчатыя вещества	Explosives	Воздушные насосы	Air Pumps
Вилляесденская бумага и парусина	Willesden Paper and Canvas	Воздушные рельсовые пути	Overhead Runways
Винтовое зацѣпленіе	Helical Gearing	Воздушные фильтры	Air Filters
Винтовые валы	Propeller Shafts.	Воздушныя камеры	Air Receivers
Винтовые реостаты (Гидравлическіе)	Propeller Starters (Hydraulic)	Волнистыя черепицы и плиты (изъ азбестоваго цемента)	Corrugated Tiles and Sheets (Asbestos-Cement)
Винторѣзные станки	Screwing Machines	Волочильныя машины	Wire-drawing Machinery
Винты (желѣзные, стальные, мѣдные, изъ морской мѣди)	Screws (Iron, Steel, Copper and Naval Brass)	Вольтметры—см. Инструменты (Электрическіе)	Voltmeters (see 'Instruments — Electrical')
Владѣльцы доковъ	Dock Owners	Войлокъ для бумажныхъ фабрикъ	Paper Makers' Felts
Владѣльцы сухихъ доковъ	Dry Dock Owners		

Листъ фабрикантовъ по вышеуказаннымъ спеціальностямъ—см. соотвѣтствующіе англійскіе заголовки въ „Подробномъ указателѣ Анонсодателей" на стр. 2821—2888.

ПО РУССКИ.	ПО АНГЛІЙСКИ.
Войлокъ для печатныхъ машинъ, машинъ для производства бумаги и набивной бумажной ткани	Felts for Printing Machinery, Paper Making, and Calico Printing Machinery
Вращающіеся конвертеры	Rotary Converters
Вспомогательныя турбинныя передачи	Geared Turbine Auxiliaries
Вторичные элементы и батареи	Storage Cells and Batteries
Вулканитъ и вулканизированная фибра	Vulcanite and Vulcanised Fibre
Выдѣлка инструментовъ, машинисты и пр.	Tool Makers, Machinists, etc.
Г	
Газгольдеры (см. газовыхъ заводовъ оборудованіе)	Gas Holders (see 'Gas Works Plant')
Газовые генераторы	Gas Producers
Газовые, нефтяные и керосиновые двигатели	Gas, Oil, and Petrol Engines
Газовые счетчики	Gas Meters
Газовыя реторты	Gas Retorts
Газовыя топки (печи) —см. Топки, плавильныя печи	Gas Furnaces (see 'Furnaces')
Газовыя трубы и приспособленія	Gas Tubes and Fittings
Газогенераторныя установки съ всасываніемъ	Suction Gas Plants
Газоочистительные вентиляторы	Gas Washing Fans
Газъ и его примѣненіе къ промышленности	Gas and its Industrial Applications
Гайки	Nuts
Гальванизаторы (машины для оцинковыванія)	Galvanisers
Гальванопластическія мастерскія	Metal (Electro Depositors)
Генераторы (электрическіе)—см. Динамо и двигатели	Generators (Electric) (see 'Dynamos and Motors')

THE
BOULTON
WATER ELEVATOR
CHAINE-HELICE AND
CARUELLE PATENTS
is a
SIMPLE, EFFICIENT and RELIABLE Apparatus to rep'ace the Deep Well Pump.

SIMPLE, because it is easiiy fixed without staging or need to descend the well.

EFFICIENT, because the only losses are those due to friction of bearings and acceleration of water.

RELIABLE, because there is a minimum number of moving parts and no valves or buckets.

Efficiencies up to 95 % have been obtained (copies of certified tests will be forwarded on request).

Will deliver a continuous stream of water in quantities up to 19,500 gallons per hour. Suitable for almost any depth.

Installations in this country up to 400 feet have been carried out.

THE

Dressing of Minerals

By HENRY LOUIS, M.A., D.Sc., A.R.S.M.

Member of the Institution of Civil Engineers; Fellow of the Institute of Chemistry of Great Britain; Fellow of the Geological Society; Member of the Institution of Mining Engineers; Emeritus Professor of Mining, Armstrong College, Newcastle-on-Tyne.

THE 'Dressing of Minerals' is a term that is intended to include all the series of operations that intervene between the extraction of a mineral from its natural deposit and its production in a condition ready for sale or for further use in the arts or manufactures; it practically covers the whole series of operations which have for their object the separation of a mass of mixed minerals into its mineralogical constituents, or the cleaning of ore constituent from the accompanying mineral or minerals which may be looked upon from the technical point of view as the impurities of the former.

The object of Professor Louis is to give an account of the theory and practice of the subject, and the present volume—the first English treatise on the subject—will prove of the greatest service to the miner or metallurgist who desires to understand the principles upon which the art is based, as also to the manufacturer who supplies the necessary appliances, and above all to the student who is preparing for either of the above professions.

SUMMARY OF CONTENTS.

I.—General Considerations. II.—Volumetric Sizing. III.—Sorting and Washing. IV.—Comminution. V.—Separation by Specific Gravity. VI.—Appliances depending essentially on Vertical Fall. VII.—Jigs. VIII.—Horizontal Current Separators. IX.—Shaking Tables. X.—Pneumatic Separation; Magnetic Separation; Electrostatic Separation; Separation by Surface Tension. XI.—Accessory Appliances. XII.—General Construction of Dressing Works.

REINFORCED CONCRETE BRIDGES

By W. L. SCOTT

ASSOC. M. INST. CIVIL ENGINEERS, CHIEF ENGINEER, CONSIDÈRE CONSTRUCTIONS, LTD.

ASSISTED By C. W. SPICER

¶ This work comprises all that is essential to guide an engineer in the adoption and the design of a bridge to suit any case ordinarily met with. In addition, it contains the best and most recent practice available, much of which is given in English for the first time. It is based on experience gained from the design and erection of hundreds of reinforced concrete bridges, embracing every type.

CONTENTS

INTRODUCTION—LOADING AND WIND PRESSURE—TEMPERATURE AND SHRINKAGE EFFECTS—INFLUENCE LINES—ARCH BRIDGES—GIRDER BRIDGES—BOWA RING GIRDER BRIDGES—TEMPORARY AND PERMANENT HINGES—FOUNDATIONS AND ABUTMENTS—DESCRIPTION OF BRIDGES—SPECIFICATION OF A REINFORCED CONCRETE BRIDGE.

ENGINEERING TRAINING

Imperial College of Science and Technology.

VISITOR—H.M. THE KING.

CITY & GUILDS (ENGINEERING) COLLEGE,

Exhibition Road, South Kensington, London, S.W. 7.

The City and Guilds (Engineering) College, the Engineering Section of the Imperial College, provides complete Courses of Instruction leading up to, and including, the highest specialised instruction with the object of fitting Students to take leading positions in the industrial world as Civil, Mechanical or Electrical Engineers, Scientific Advisers, Investigators or Experts in the Engineering industries, and for those already qualified who desire to take up more advanced courses of training and research in connection with the branches of Engineering in which they are specially interested.

The Departments of the College are as follows :—

ENGINEERING, MECHANICAL AND MOTIVE POWER—

Under the direction of Prof. Dalby, F.R.S., M.Inst.C.E.

ENGINEERING, CIVIL, AND SURVEYING—

Under the direction of Prof. Dixon, M.Inst.C.E.

ENGINEERING, ELECTRICAL—

Under the direction of Prof. Fortescue, M.I.E.E.

MATHEMATICS—

Under the direction of Prof. Chapman, F.R.S.

The following Diplomas are awarded to Students who satisfactorily complete a full Course of from two to four years :—

The Associateship of the City and Guilds of London Institute (A.C.G.I.).

For admission to the Courses qualifying for this Diploma candidates are required to pass one of the Entrance or Matriculation Examinations of the College held in April and September (application to be made not later than the first Friday in April or the first Monday in September respectively) ; or to have passed the Matriculation of the University of London in certain subjects.

The Diploma of the Imperial College (D.I.C.).

(For advanced specialised or fourth-year work.)

Further information and the Prospectus of the College may be obtained on application to the Registrar.

LONDON

ENGINEERING TRAINING

UNIVERSITY OF LONDON
KING'S COLLEGE.

FACULTY OF ENGINEERING

Complete courses of study, extending over either three or four years, are arranged in :—

CIVIL, MECHANICAL AND ELECTRICAL ENGINEERING

for the Engineering Degrees of the University of London, and for the Diploma and Certificate of the College.

The four years' Course provides, in addition to the academic training, opportunity for practical training in "Works."

HEADS OF DEPARTMENTS

Professor G. COOK, D.Sc., M.I.Mech.E., A.M.Inst.C.E. Mechanical Engineering.
C. A. GENEVE, B.Sc., A.M.I.Mech.E. Senior Lecturer.
Professor A. H. JAMESON, M.Sc., M.Inst.C.E. Civil Engineering. (Dean)
C. H. LOBBAN, B.Sc., A.M.Inst.C.E. Senior Lecturer.
Professor E. WILSON, M.Inst.C.E., M.I.E.E. Electrical Engineering.
F. S. ROBERTSON, M.I.E.E. Lecturer.
Professor S. A. F. WHITE, M.A. Mathematics.
Professor A. E. OLLIFFE, M.A. Mathematics.

Considerable Extensions have been made in the Engineering Department. These include a large additional drawing-office, lecture room, and laboratory for Hydraulics and Strength of Materials in the Civil and Mechanical Departments; and research rooms, including Wireless Telegraphy, in the Electrical Engineering Department. Large additions have been made to the equipment of the Laboratories in the three Departments for purposes of teaching and research.

There is a College Hostel and a large Athletic Ground.

For full information apply to
The SECRETARY, King's College, Strand, W.C. 2.

LONDON

ENGINEERING TRAINING

The Polytechnic, 309 Regent St., W. 1.

President	SIR KYNASTON STUDD.
Vice Presidents	THE RT. HON. SIR DOUGLAS McGAREL HOGG, K.C., M.P. MAJOR ROBERT MITCHELL, C.B.E., J.P.

Head of Electrical Engineering Dept.	PHILIP KEMP, M.Sc.Tech., M.I.E.E.

Day Courses.

Courses extending over three years are offered in Mechanical, Electrical and Motor Engineering. Each Course embraces lectures, laboratory, and workshop drawing-office practice.

The Courses in Mechanical and Electrical Engineering are recognised by the Institutions of Mechanical and Electrical Engineers respectively and the Board of Education for the award of Senior and Advanced National Diplomas.

School Diplomas are awarded in all branches.

Entrance Examinations are held in July and September.

Evening Classes.

Courses of Study are offered in Civil, Mechanical, Electrical, Motor and Gas Engineering. These are designed to afford a thorough training, on an advanced standard, in the science and practice of Engineering. The work undertaken covers the requirements of the examinations for admission to the several Engineering Institutions.

The Courses in Mechanical and Electrical Engineering are recognised for the award of National Certificates.

Prospectuses, and full particulars, may be obtained from the Director of Education, The Polytechnic, 309 Regent Street, W. 1.

LONDON

ENGINEERING TRAINING

The Crystal Palace School of Practical Engineering

Founded 1872.

Mechanical and Civil Divisions.

President: **J. W. WILSON**, M.Inst.C.E., M.Inst.Mech.E., F.S.E.
Principal: **MAURICE WILSON**, A.M.Inst.C.E., Past President, Society of Engineers. *Vice-Principal*: **F. C. P. LAWRENCE**, M.S.E., A.M.Inst.Struct.E.

ASSISTED BY A STAFF OF LECTURERS AND INSTRUCTORS.

The School may be Inspected on application to the Principal, from whom all further information may be obtained.

This School was established for the purpose of providing Students of any branch of Engineering with thorough practical and theoretical instruction in the rudiments of the profession and in the manipulation of materials. The institution has since been largely extended.

The School is approved by the Council of the Institution of Civil Engineers' and Students who pass through its complete course and otherwise comply with the current regulations of the Institution are eligible for their Examinations; they are also eligible for election as Students of the Institution of Mechanical Engineers, Associates of the Society of Engineers, etc.

The usual age for admission to the School is 16 to 17 years, but there is no limit as to the age of Students. They may commence work at the beginning of any term.

Mechanical Engineering (First Year).

The Students spend one Term each in the Drawing Office, the Pattern Shop and Foundry, and the Fitting and Smith's Shop, besides attending Lectures on 'Steam and the Steam Engine,' 'Railways: their Construction and Appliances,' 'Materials and their Manufacture,' and other Special Subjects.

Civil Engineering (Second Year).

The first Term in this section is devoted to Practical Preparation by actual Levelling, Surveying, Theodolite work, etc., of Plans for a complete Public Work, and the necessary Plans, Estimates, etc., for Parliament.

The second Term is devoted to the Preparation of Working Plans, Calculations, Estimates, etc., of the said Work for the Contractors.

The third Term is utilised for Original Designing, Theory of Structures, and other necessary Calculations, Specifications, etc., for Bridge, Reinforced Concrete and other Work, and reporting upon existing Engineering Works.

Debates are held to afford Students an opportunity of gaining confidence in public professional speaking.

At the meetings of the 'Crystal Palace Engineering Society' (affiliated to the Society of Engineers) Students read and discuss papers on Professional subjects. Professional visits to Engineering Works are made from time to time.

Of the Students who have passed through the School, many have obtained appointments as Chief Engineers at home and abroad; and over 1,300 are employed in Engineering Work in various Countries in the World.

LONDON

ENGINEERING TRAINING

University of Birmingham.

Chancellor—THE VISCOUNT CECIL OF CHELWOOD.
Vice-Chancellor—SIR GILBERT BARLING, BART., C.B., F.R.C.S.
Principal—C. GRANT ROBERTSON, M.A., C.V.O.
Vice-Principal—SIR WILLIAM ASHLEY, M.A., M.Com.
Secretary—C. G. BURTON.

Departments of Civil, Mechanical & Electrical Engineering.

The FULL COURSES EXTEND OVER FOUR YEARS, and students who enter after Matriculation and who pass successfully the Examinations at the end of each year WILL BE ENTITLED to the DEGREE of BACHELOR OF SCIENCE in the branch of Engineering to which they devote themselves.

The Technical Engineering Classes include:—

Lectures on the Strength of Materials, Theory of Steam, Gas, and other Heat Engines, Hydraulics, Machine Design, Strength of Structures, Distribution of Power.

Drawing: Design of Tools, Prime Motors, Dynamos, and other forms of Machinery.

Courses in Civil Engineering, including Constructional Work in Masonry and Steel, Railway Work, Dams, Bridges, and Water Engineering.

Field Work: Practical Surveying in the Field throughout the Summer Term.

Engineering Laboratory: Determination of the Strength of Materials, including Compressive, Bending, Tensile, and Torsion Tests, Experimental Study of the Steam Engine and Boiler, Frictional Efficiency Tests, the Flow of Water over Weirs and through Orifices, etc.

Lectures and Demonstrations on all branches of Electrical Engineering.

Electrical Laboratory: Testing of Continuous and Alternate Current Machinery: Electrical Instruments, Meters, Lamps and Batteries: Insulation and Magnetic Testing Work.

The Courses also include Instruction in Mathematics, Physics, Chemistry, Geology, and Metallurgy.

For detailed Syllabus, with full particulars of University Regulations, Lectnre and Laboratory Courses, Fees, Scholarships, etc., apply to the Secretary.

BIRMINGHAM

ENGINEERING EDUCATION

TECHNICAL COLLEGE BRADFORD

DAY COURSES

FULL-TIME (DAY) COURSES extending over three or four years, and leading to the Diploma of the College, are arranged in the following Departments:—

TEXTILE INDUSTRIES
CHEMISTRY
DYEING
MECHANICAL ENGINEERING
CIVIL ENGINEERING, ARCHITECTURE and BUILDING
ELECTRICAL ENGINEERING
BIOLOGY

Special facilities are available for advanced study and research.

EVENING COURSES

PART-TIME (EVENING) COURSES are also arranged, on the successful completion of which students are awarded Senior and Advanced Course Certificates.

Further particulars and prospectuses may be obtained on application to THE PRINCIPAL, Technical College, Bradford.

BRADFORD

ENGINEERING TRAINING

Heriot-Watt College,

EDINBURGH.

Governors—THE GOVERNORS OF GEORGE HERIOT'S TRUST.

Chairman—THE RIGHT HON. THE LORD PROVOST.

Convener of Heriot-Watt College Committee—W. A. TAIT, Esq., M.Inst.C.E.

Principal—A. P. LAURIE, M.A., D.Sc., F.R.S.E., sometime Fellow of King's College, Cambridge.

DAY TECHNICAL COLLEGE

COURSES OF INSTRUCTION IN

MECHANICAL ENGINEERING, ELECTRICAL ENGINEERING, APPLIED CHEMISTRY, MINING.

The Heriot-Watt College offers complete Courses of Instruction in these subjects, and a Diploma or Certificate at the end of the Course.

The complete Diploma Courses in Mechanical Engineering and Electrical Engineering last over three years, and in Applied and Analytical Chemistry over four years.

The Diploma Course in Mining (Coal, Metalliferous and Oil) lasts over three years.

Arrangements have been made with local Engineering Firms for shortened apprenticeships for students who hold the Diploma of the College.

The Associateship of the College in Chemistry is recognised by the Institute of Chemistry as a qualification exempting students from the examinations for the Associateship of the Institute of Chemistry. In the Chemistry Department there are also Courses in Bio-Chemistry, and in Pharmaceutics for the Professional Examinations of the Pharmaceutical Society.

Special arrangements have been made for **POST-GRADUATE COURSES** in **ELECTRICAL ENGINEERING, PRIME MOVERS,** and **APPLIED CHEMISTRY.** Students wishing to take these post-graduate Courses must either hold the B.Sc. of some University or the Diploma of the Heriot-Watt College or of the Royal Technical College, Glasgow.

There is also a Course extending over two Winter Sessions for Clerks of Works, Builders' Clerks, and Surveyors' Apprentices.

EVENING CLASSES.—Advanced Classes in various Departments of Pure and Applied Science, Commerce, and Languages, which will prove of use to students who have already taken a Degree or who are studying for a Degree, are held in the College in the Evening.

FEES.—Day Classes. Composition Fees for Diploma Courses, £23 to £31 10*s.* per annum. **Evening Classes,** 7*s.* 6*d.* to £3 3*s.*

All particulars regarding the College Classes, both Day and Evening, can be obtained from the PRINCIPAL at the College.

For the Scheme for Degrees in Civil, Electrical and Mechanical Engineering, Mining and Metallurgy, and Technical Chemistry arranged with the University of Edinburgh, see University Calendar, or the Calendar of Heriot-Watt College.

EDINBURGH

ENGINEERING TRAINING

The Royal Technical College, GLASGOW.

The College is affiliated to the University of Glasgow, and the Degrees of the University in Engineering and Applied Chemistry are open to its students.

The Diploma of the College is granted in the following Departments :—

CIVIL ENGINEERING.
Professor GEORGE MONCUR, B.Sc., M.Inst.C.E.

MECHANICAL ENGINEERING.
Professor A. L. MELLANBY, D.Sc., M.I.Mech.E.
Associate Professor WM. KERR, Ph.D., A.R.T.C.

ELECTRICAL ENGINEERING.
Professor STANLEY PARKER SMITH, D.Sc., M.I.E.E.

MINING ENGINEERING.
Professor DANIEL BURNS, M.Inst.M.E.

NAVAL ARCHITECTURE.
Lecturer, Mr. WM. M. GRAY, B.Sc., M.I.N.A.

CHEMISTRY.
Director of the School of Chemistry, and 'Young' Professor of Technical Chemistry—THOMAS GRAY, D.Sc., LL.D., Ph.D., F.I.C.
Professor of Organic Chemistry—FORSYTH J. WILSON, D.Sc., Ph.D., F.I.C.
Professor of Inorganic and Analytical Chemistry—ROBERT M. CAVEN, D.Sc., F.I.C.

METALLURGY.
Professor JOHN H. ANDREW, D.Sc.

BUILDING.
Professor CHARLES GOURLAY, B.Sc., F.R.I.B.A.

TEXTILE MANUFACTURE.
Lecturer, Mr. WM. WATSON.

DYEING.
Lecturer, Mr. ALEC B. STEVEN, B.Sc., F.I.C.

SUGAR MANUFACTURE.
Lecturer, Mr. T. H. P. HERIOT, F.I.C., F.C.S.

A Course for a Joint Diploma in Architecture has been arranged in conjunction with the Glasgow School of Art.

The Diploma Course extends over either three or four sessions, and the fee per session is Twenty-five Guineas.

Full Courses of Instruction are also provided in the Schools of Navigation, Pharmacy and Bakery.

Prospectuses (free) will be sent on application to the Director.

LEEDS

ENGINEERING TRAINING

The University of Liverpool

FACULTY OF ENGINEERING.

DEAN: Professor C. O. BANNISTER, M.Eng., Assoc. R.S.M., F.I.C., M.Inst.M.M.

THE University awards the degrees of B.Eng., M.Eng., D.Eng., Ph.D., and a Certificate and Diploma in Engineering.

Degree candidates must pass an approved Matriculation Examination. Candidates for a Certificate (which leads to a Diploma) must have: (i) Been engaged in Practical Engineering. (ii) Followed approved courses in a Technical School.

The courses are designed for students desiring to qualify as MECHANICAL, ELECTRICAL, CIVIL or MARINE ENGINEERS, as NAVAL ARCHITECTS and METALLURGISTS or METALLURGICAL ENGINEERS. These courses cover the subjects of Examination for Associate Membership of the Institutions of Civil, Mechanical, and Electrical Engineers. The Institutions named, subject to certain conditions, accept the degree of B.Eng. in lieu of part, and in some cases the whole, of the examinations for Associate Membership. The various departments are housed in commodious and well equipped buildings, and provide ample facilities for research.

A prospectus of the Faculty, giving particulars of courses and a large number of Entrance and Post-graduate Scholarships, may be had on application to the undersigned,

EDWARD CAREY, *Registrar.*

LIVERPOOL

ENGINEERING TRAINING

LOUGHBOROUGH COLLEGE,
LEICESTERSHIRE.

H. SCHOFIELD, Ph.D. Lond., B.Sc. (Hons.) Lond., A.R.C.Sc. Lond., M.I.Mech.E., Assoc.M.Inst.C.E., D.I.C., F.Inst.P., Principal.

DEPARTMENTS OF MECHANICAL, CIVIL, ELECTRICAL, AUTOMOBILE, CHEMICAL AND COMMERCIAL ENGINEERING.

DEGREE AND DIPLOMA COURSES are arranged in the Theory and Practice of Engineering.

The Workshops of the College provide accommodation for 500 Students working at the same time.

The equipment is on most modern and comprehensive lines, and comprises Plant for Turning, Fitting, Milling, Grinding, Automatic Lathe Operating and Tool Setting, Tool and Gauge Making, Foundry Work, Pattern Making, Drawing Office Work, Heat Treatment, Viewing and Testing of all kinds, including Micrography and Radiography.

None but first-class work of a productive character is undertaken by the Students, working under the skilled supervision of a fully qualified Technical Staff.

The complete Course covers a period of five years, during which Works training in all the above sections may be given, and this will be accompanied by a full Theoretical Course of Instruction in the College Lecture Rooms and Laboratories.

Intending Students should be at least sixteen years of age, and have had a good Public School or Secondary Education.

The College Fees are:—Departments of Mechanical, Civil, Electrical and Automobile Engineering, £150 per annum, or £50 per term. Departments of Chemical and Commercial Engineering, £105 per annum, or £35 per Term. These charges include Tuition and Sports Fees, Subscriptions to the College Union and Reference Library, and full Board and Residence, during Term, in the College Residential Halls.

The College Calendar (illustrated), with full particulars, will be forwarded upon application to the Registrar.

ENGINEERING TRAINING

University College of Nottingham.

Principal - - W. H. HEATON, M.A.

MECHANICAL, ELECTRICAL, and MINING ENGINEERING.

Heads of Departments:

Engineering Professor C. H. BULLEID, M.A., A.M.I.C.E.
Mining - - Professor W. H. McMILLAN, B.Sc., M.I.M.E.
Director of the Sub-Department of Electrical Engineering:
H. COTTON, M.B.E., A.M.I.E.E., M.Sc.

DEGREE COURSES.

The College provides complete courses of study extending over three or four years for the Degrees of London University in Engineering and Mining.

DIPLOMA COURSES.

The Course for the Associateship of the University College of Nottingham in Engineering, Mining, or Mine Surveying extends over three years. Short courses for special purposes can be arranged.

The subjects comprised in the above courses are: Mathematics, Physics, Chemistry, Metallurgy, Machine Drawing and Design, Heat Engines, Hydraulics, Strength of Materials, Theory of Structures, Surveying, Theory of Machines, Electrical Technology and Design, Geology, Petroleum Technology, Mining, Mine Surveying, etc.

The Mechanical and Electrical Engineering and Mining Laboratories are fully equipped with the latest apparatus and testing machinery. Metal working tools of all types are provided in the workshops.

ENTRANCE EXAMINATION.

For those who have not passed the London University Matriculation or an equivalent examination an Entrance Examination is held in July and September.

Prospectus and all particulars may be obtained from
THE REGISTRAR.
